What is a topological theory?

Walter Tholen, York University

It is the tenet of monoidal topology that topological structures may be uniformly described as lax-algebraic structures, with the notion of monoid in a monoidal category playing a pivotal role. Furthermore, lax modifications of the syntax used in algebra furnish the syntax used in topology, most prominently through lax extensions of Set-monads to quantale-valued relations.

Dirk Hofmann observed that such extensions are determined by a lax algebraic structure on one specific object (the quantale in question) and, turning the tables, made this fact the cornerstone of his notion of topological theory (2007, Advances in Mathematics).

In this talk we address potential modifications of his notion, which appear to be crucial when aiming to move beyond quantales and Set-based monads.
