

STRONG CONVERGENCE RATES FOR THE ESTIMATION OF A COVARIANCE OPERATOR FOR ASSOCIATED SAMPLES

CARLA HENRIQUES AND PAULO EDUARDO OLIVEIRA

ABSTRACT: Let X_n , $n \geq 1$, be a strictly stationary associated sequence of random variables, with common continuous and bounded distribution function F . Using histogram type estimators we consider the estimation of the two-dimensional distribution function of (X_1, X_{k+1}) as well as the estimation of the covariance function of the limit empirical process induced by the sequence X_n , $n \geq 1$. Assuming a convenient decrease rate of the covariances $\text{Cov}(X_1, X_{n+1})$, $n \geq 1$, we derive uniform strong convergence rates for those estimators. The condition on the covariance structure of the variables is satisfied either if $\text{Cov}(X_1, X_{n+1})$ decreases polynomially or if it decreases geometrically, but as we could expect, under the latter condition we are able to establish faster convergence rates. For the two-dimensional distribution function the rate of convergence derived under a geometrical decrease of the covariances is close to the optimal rate for independent samples.

KEYWORDS: association, empirical process, histogram estimator, stationarity.

AMS SUBJECT CLASSIFICATION (2000): 62G20, 62G05, 62G30.

1. Introduction, assumptions and definitions

A sequence of random variables X_n , $n \geq 1$, is said to be associated if for any $m \in \mathbb{N}$ and any two real-valued coordinatewise nondecreasing functions f and g it holds

$$\text{Cov}\left(f(X_1, \dots, X_m), g(X_1, \dots, X_m)\right) \geq 0,$$

whenever this covariance exists. This dependence concept, introduced in Esary, Proschan and Walkup [2], occurs naturally in every framework that depend on monotone transformations of random variables such as reliability theory, censored or truncated sampling. The dependence notion appears also in statistical mechanics referred as FKG inequalities.

Let $Z_n(t) = n^{-1/2} \sum_{i=1}^n (I_{(-\infty, t]}(X_i) - F(t))$ be the empirical process induced by the random variables $X_n, n \geq 1$, with common continuous distribution function F , where I_A represents the indicator function of the set A . For associated random variables, under suitable assumptions on their covariance structure (see Louhichi [7] and Oliveira and Suquet [11, 12] for the best known results on the covariance decrease rates for the convergence in $D[0, 1]$, $L^2[0, 1]$ or $L^p[0, 1]$, respectively), Z_n converges weakly to a centered Gaussian process with covariance function

$$\begin{aligned} \Gamma(s, t) &= F(s \wedge t) - F(s)F(t) \\ &+ \sum_{k=1}^{\infty} (\mathbb{P}(X_1 \leq s, X_{k+1} \leq t) - F(s)F(t)) \\ &+ \sum_{k=1}^{\infty} (\mathbb{P}(X_1 \leq t, X_{k+1} \leq s) - F(s)F(t)). \end{aligned} \quad (1)$$

As it is well known, the asymptotic behaviour of the empirical process is of great interest in many statistical applications. In several fields of statistics we often find transformations of the empirical process for which it is of interest to characterize their limit in distribution. The results about the asymptotic behavior of the empirical process are a valuable tool to accomplish this. Some classic examples are several goodness of fit tests statistics, such as the Kolmogorov-Smirnov and the Cramér-von Mises ω^2 test statistics, which are, respectively, the sup-norm and the $L^2[0, 1]$ norm of the uniform empirical process (the empirical process of $U[0, 1]$ random variables). Another example of application may be found in Shao and Yu [15], who are interested on integral functionals of the empirical process and on the mean residual life processes in reliability.

The above comments and remarks motivated the interest on the estimation of the the covariance function (1). For this we will estimate the terms appearing in the series and sum a convenient number of these estimates to approximate Γ . We will concentrate on histogram estimators and on proving uniform strong convergence rates.

The estimator for $F_k(s, t)$, the distribution function of (X_1, X_{k+1}) , is defined by

$$\widehat{F}_{k,n}(s, t) = \frac{1}{n-k} \sum_{i=1}^{n-k} (I_{(-\infty, s]}(X_i) I_{(-\infty, t]}(X_{i+k})). \quad (2)$$

The asymptotic properties of this estimator were studied by Henriques and Oliveira [4], who derived conditions on the covariance structure of the sequence X_n , $n \geq 1$, for the uniform almost sure consistency of this estimator and for the convergence in distribution of the finite dimensional distributions. Furthermore, the convergence rate of the mean square error was characterized. However, no rates were provided for the uniform strong convergence.

Combining the estimator $\widehat{F}_{k,n}(s, t)$ with the empirical distribution function defined by $\widehat{F}_n(s) = n^{-1} \sum_{j=1}^n I_{(-\infty, s]}(X_j)$, we obtain a natural estimator for the terms $\varphi_k(s, t) = F_k(s, t) - F(s)F(t)$, namely,

$$\widehat{\varphi}_{k,n}(s, t) = \widehat{F}_{k,n}(s, t) - \widehat{F}_n(s)\widehat{F}_n(t). \quad (3)$$

The estimators for the infinite sum in the expression of $\Gamma(s, t)$ and for $\Gamma(s, t)$ itself are, respectively,

$$\sum_{k=1}^{a_n} \widehat{\varphi}_{k,n}(s, t), \quad (4)$$

and

$$\widehat{\Gamma}_n(s, t) = \widehat{F}_n(s \wedge t) - \widehat{F}_n(s)\widehat{F}_n(t) + \sum_{k=1}^{a_n} \left(\widehat{\varphi}_{k,n}(s, t) + \widehat{\varphi}_{k,n}(t, s) \right). \quad (5)$$

where $a_n \rightarrow +\infty$ is such that $\frac{a_n}{n} \rightarrow 0$.

It is well known that the covariance structure of a sequence of associated random variables highly determines its approximate independence (see, for example, Newman [10] for a number of results regarding this). As a natural consequence, when dealing with associated samples it is common to have assumptions on the covariance structure of the random variables. To introduce the assumptions to be considered in the results of this article we define

$$u(n) = \sum_{j=n+1}^{\infty} \text{Cov}^{1/3}(X_1, X_j). \quad (6)$$

Note the exponent $1/3$ on our definition of $u(n)$. In the literature on associated variables this exponent is usually not present. Here it is convenient to include it in the definition of $u(n)$, as we are concerned with indicators of the associated variables rather than in the variables themselves. The need for this exponent is explained by the inequality (7) below.

We now introduce two general assumptions to be used throughout the article.

- (S1) X_n , $n \geq 1$, is an associated and strictly stationary sequence of random variables having density function bounded by B_0 ; let $B_1 = 2 \max(2/\pi^2, 45B_0)$.
- (S2) Let $\theta > 0$. There exists a constant $C_0 > 0$ such that $u(n) \leq C_0 n^{-\theta}$, for all $n \geq 1$.

Remark that under (S2),

$$u(0) = \sum_{j=1}^{\infty} \text{Cov}^{1/3}(X_1, X_j) < \infty.$$

In order to be able to identify explicit convergence rates for the estimators, we consider the following assumptions on the decay rate of the covariances of the random variables.

(G) Suppose that there exist $a_0 > 0$ and $a > 1$, such that $\text{Cov}(X_1, X_n) = a_0 a^{-n}$.

(P) Suppose that $\text{Cov}(X_1, X_n) = a_0 n^{-a}$, with $a_0 > 0$ and $a > 3$.

Note that, under (G) assumption (S2) holds for all $\theta > 0$, while under (P) assumption (S2) holds for all $\theta \in (0, a/3 - 1]$.

Under (S1) we may apply relation (21) in Newman [9] and Corollary to Theorem 1 in Sadikova [14] to find (see Lemma 2.6 in Roussas [13] for details)

$$\text{Cov}(I_{(-\infty, s]}(X_i), I_{(-\infty, t]}(X_j)) \leq B_1 \text{Cov}^{1/3}(X_i, X_j), \quad s, t \in \mathbb{R}, \quad (7)$$

where B_1 is defined in (S1).

In Henriques and Oliveira [5], the authors have already derived uniform strong convergence rates for the estimators studied here. The method used in [5] was based on exponential inequalities, and required a quite fast decay of $\text{Cov}(X_1, X_n)$. In fact, the assumptions in [5] on the covariance structure hold under a geometric decay rate of the covariances (G), but not under a polynomial decay (P). More precisely, under (G), it was established that the estimators $\widehat{F}_{k,n}$ and $\widehat{\varphi}_{k,n}$ are uniformly strong consistent with a convergence rate faster than $n^{-\alpha}$, where $0 < \alpha < 1/3$ may be chosen as close to $1/3$ as desired. Furthermore, also under (G), it is shown that the estimators for the infinite sum $\sum_{k=1}^{\infty} \varphi_k(s, t)$ and for $\Gamma(s, t)$ converge almost surely at a rate faster than $\frac{\log n}{n^\alpha}$, where again $0 < \alpha < 1/3$ may be chosen as close to $1/3$ as desired. Here, we will improve these results in two ways. First we will be able to characterize the rate of convergence not only under (G) but also under (P); secondly, under (G) we will derive faster rates of convergence than those

mentioned previously. Furthermore, for the estimation of $F_k(s, t)$, under (G), we obtain convergence rates which approach the best possible ones for independent samples (see, in Section 3, the comment just before Theorem 3.3). The starting point for the derivation of these rates is a moment inequality for associated random variables by Shao and Yu [15]. Our method was inspired by Masry [8], who uses moment inequalities to obtain convergence rates for the estimation of the density and its derivatives, considering also associated samples.

In Section 2 we will present some auxiliary results needed to establish the above mentioned convergence rates. The moment inequality referred earlier is included in this section. The results establishing rates of uniform strong convergence are presented in Sections 3 and 4, Section 3 dealing with the estimators $\widehat{F}_{k,n}(s, t)$ and $\widehat{\varphi}_{k,n}(s, t)$ and Section 4 with the estimators $\sum_{k=1}^{a_n} \widehat{\varphi}_{k,n}(s, t)$ and $\widehat{\Gamma}_n(s, t)$.

2. Auxiliary results

As mentioned before, the convergence rates that will be established in this article follow from a moment inequality, which is stated in the next lemma. This result is a version of Theorem 4.2 of Shao and Yu [15], for bounded and strictly stationary random variables, where we took (referring to notation of [15]) f to be the identity function, $r = \infty$, $\theta = \frac{p-2}{2}$ and $\varepsilon = \frac{p}{2} - 1$.

Lemma 2.1. (Shao and Yu [15]) *Let Y_n , $n \geq 1$, be a strictly stationary sequence of associated random variables satisfying $E(Y_j) = 0$ and $|Y_j| \leq M < \infty$, for $j \in \mathbb{N}$. Let $p > 2$ and assume that there exists a constant $C_1 > 0$ such that, for each $n \in \mathbb{N}$,*

$$\sum_{j=n+1}^{\infty} \text{Cov}(Y_1, Y_j) \leq C_1 n^{-\frac{p-2}{2}}.$$

Then, there exists a constant $K = K(p)$ such that, for all $n \in \mathbb{N}$,

$$E \left| \sum_{i=1}^n Y_i \right|^p \leq K n^{p/2} \left(E |Y_1|^p + \left(\max_{i \leq n} \sum_{j=1}^n \text{Cov}(Y_i, Y_j) \right)^{p/2} + M^{p-2} C_1 \right).$$

Based on the previous result we prove an inequality that will be essential for proving our convergence rates.

Lemma 2.2. *Let $k \in \mathbb{N}_0$ be fixed and ε_n a sequence of positive numbers. Suppose (S1) and (S2) are satisfied with $\theta = \frac{p-2}{2}$, for some $p > 2$, for the later. Then, there exists a constant $K = K(p)$ such that, for each $n > k$ and $s, t \in \mathbb{R}$,*

$$\mathbb{P} \left(\left| \widehat{F}_{k,n}(s, t) - F_k(s, t) \right| > \varepsilon_n \right) \leq \frac{D}{\varepsilon_n^p (n-k)^{p/2}},$$

with

$$\begin{aligned} D &= K \left(1 + (10B_1u(0))^{p/2} + c_k \right), \\ c_k &= B_1 \max \{ 4C_0(k+1)^\theta, 3C_0 + 2u(0)k^\theta \}. \end{aligned}$$

Proof: For each $n \in \mathbb{N}$ and fixed $s, t \in \mathbb{R}$ define

$$W_{k,n} = I_{(-\infty, s]}(X_n)I_{(-\infty, t]}(X_{k+n}) - F_k(s, t),$$

so that we can write

$$\widehat{F}_{k,n}(s, t) - F_k(s, t) = \frac{1}{n-k} \sum_{i=1}^{n-k} W_{k,i}.$$

Given (S1), since the $W_{k,n}$ are decreasing functions of the variables X_n , the sequence $W_{k,n}$, $n \geq 1$, is associated and strictly stationary. Furthermore, $|W_{k,n}| \leq 1$ and $\mathbb{E}(W_{k,n}) = 0$, for each $n \geq 1$.

We want to apply Lemma 2.1 to the sequence $W_{k,n}$, $n \geq 1$, so that we need to check that there exists a positive constant C_1 such that, for all $m \geq 1$,

$$\sum_{j=m+1}^{\infty} \text{Cov}(W_{k,1}, W_{k,j}) \leq C_1 m^{-\theta}. \quad (8)$$

Applying a classical inequality by Lebowitz [6] and (7) we obtain

$$\begin{aligned} \text{Cov}(W_{k,1}, W_{k,j}) &\leq B_1 \left[\text{Cov}^{1/3}(X_1, X_j) + \text{Cov}^{1/3}(X_1, X_{k+j}) + \right. \\ &\quad \left. + \text{Cov}^{1/3}(X_{k+1}, X_j) + \text{Cov}^{1/3}(X_{k+1}, X_{k+j}) \right]. \end{aligned} \quad (9)$$

Thus, on account of (S2), we get, for every $m > k$,

$$\begin{aligned} \sum_{j=m+1}^{\infty} \text{Cov}(W_{k,1}, W_{k,j}) &\leq 2B_1u(m) + B_1u(m+k) + B_1u(m-k) \\ &\leq 2B_1C_0m^{-\theta} + B_1C_0(m+k)^{-\theta} + B_1C_0(m-k)^{-\theta} \\ &\leq 4B_1C_0(m-k)^{-\theta} \\ &\leq 4B_1C_0(k+1)^\theta m^{-\theta}, \end{aligned}$$

where, for the last step we used the fact that $\left\{ \left(\frac{m}{m-k} \right)^\theta, m > k \right\}$ is a non-increasing sequence in m , so bounded above by the first term.

Moreover, for any $m \leq k$, we obtain from (9),

$$\begin{aligned}
& \sum_{j=m+1}^{\infty} \text{Cov}(W_{k,1}, W_{k,j}) \\
& \leq 2B_1u(m) + B_1u(m+k) + B_1 \sum_{j=m+1}^{\infty} \text{Cov}^{1/3}(X_{k+1}, X_j) \\
& \leq 2B_1u(m) + B_1u(m+k) \\
& \quad + B_1 \left(\sum_{j=1}^{k-m+1} \text{Cov}^{1/3}(X_1, X_j) + \sum_{j=2}^{\infty} \text{Cov}^{1/3}(X_1, X_j) \right) \\
& \leq 2B_1u(m) + B_1u(m+k) + 2B_1u(0).
\end{aligned}$$

Again using (S2) we get, for every $m \leq k$,

$$\begin{aligned}
\sum_{j=m+1}^{\infty} \text{Cov}(W_{k,1}, W_{k,j}) & \leq 2B_1C_0m^{-\theta} + B_1C_0(m+k)^{-\theta} + 2B_1u(0) \\
& \leq 3B_1C_0m^{-\theta} + 2B_1u(0) \\
& = (3B_1C_0 + 2B_1u(0)m^\theta)m^{-\theta} \\
& \leq (3B_1C_0 + 2B_1u(0)k^\theta)m^{-\theta}.
\end{aligned}$$

Setting $c_k = B_1 \max\{4C_0(k+1)^\theta, 3C_0 + 2u(0)k^\theta\}$, (8) then follows with $C_1 = c_k$.

Then, by Lemma 2.1, there exists a constant $K = K(p)$ such that, for all $m \geq 1$,

$$\mathbb{E} \left| \sum_{i=1}^m W_{k,i} \right|^p \leq K m^{p/2} \left(1 + \left(2 \sum_{j=1}^m \text{Cov}(W_{k,1}, W_{k,j}) \right)^{p/2} + c_k \right), \quad (10)$$

given the stationarity of $W_{k,n}$, $n \geq 1$, and the fact that $|W_{k,n}| \leq 1$.

On account of (9) we obtain,

$$\begin{aligned}
\sum_{j=1}^m \text{Cov}(W_{k,1}, W_{k,j}) &\leq 2B_1 \sum_{j=1}^m \text{Cov}^{1/3}(X_1, X_j) + B_1 \sum_{j=1}^m \text{Cov}^{1/3}(X_1, X_{k+j}) \\
&\quad + B_1 \sum_{j=1}^m \text{Cov}^{1/3}(X_{k+1}, X_j) \\
&\leq 2B_1 u(0) + B_1 \sum_{j=k+1}^{\infty} \text{Cov}^{1/3}(X_1, X_j) \\
&\quad + B_1 \left(\sum_{j=1}^k \text{Cov}^{1/3}(X_{k+1}, X_j) + \sum_{j=k+1}^{\infty} \text{Cov}^{1/3}(X_{k+1}, X_j) \right) \\
&\leq 2B_1 u(0) + B_1 u(0) + 2B_1 u(0) = 5B_1 u(0).
\end{aligned}$$

From (10) it now follows that, for all $m \geq 1$,

$$\mathbb{E} \left| \sum_{i=1}^m W_{k,i} \right|^p \leq K \left(1 + (10B_1 u(0))^{p/2} + c_k \right) m^{p/2}.$$

Finally, using the Markov inequality we find, for all $n > k$,

$$\begin{aligned}
\mathbb{P} \left(\left| \widehat{F}_{k,n}(s, t) - F_k(s, t) \right| \geq \varepsilon_n \right) &\leq \left(\frac{1}{\varepsilon_n(n-k)} \right)^p \mathbb{E} \left| \sum_{i=1}^{n-k} W_{k,i} \right|^p \\
&\leq \frac{D}{\varepsilon_n^p (n-k)^{p/2}},
\end{aligned}$$

with $D = K \left(1 + (10B_1 u(0))^{p/2} + c_k \right)$. ■

For the formulation of the next results we need to introduce some additional notation. Let t_n be a sequence of positive integers such that $t_n \rightarrow +\infty$. For each $n \in \mathbb{N}$ and each $i = 1, \dots, t_n$, put $x_{n,i} = Q(i/t_n)$, where Q is the quantile function of F . Define then, for $n, k \in \mathbb{N}$,

$$D_{n,k} = \sup_{s,t \in \mathbb{R}} \left| \widehat{F}_{k,n}(s, t) - F_k(s, t) \right|,$$

and

$$D_{n,k}^* = \max_{i,j=1,\dots,t_n} \left| \widehat{F}_{k,n}(x_{n,i}, x_{n,j}) - F_k(x_{n,i}, x_{n,j}) \right|.$$

To prove an uniform version of the preceding lemma we will apply the following result which is proved in Theorem 2 of Henriques and Oliveira [4].

Lemma 2.3. *If the sequence X_n , $n \geq 1$, satisfies (S1), then, for each $n \in \mathbb{N}$ and each $k \in \mathbb{N}_0$,*

$$D_{n,k} \leq D_{n,k}^* + \frac{2}{t_n} \quad a.s..$$

Lemma 2.4. *Let ε_n and t_n be two sequences of positive numbers such that $t_n \rightarrow +\infty$ and $\varepsilon_n t_n \rightarrow +\infty$, and $k \in \mathbb{N}_0$ be fixed. Suppose (S1) holds and (S2) is satisfied with $\theta = \frac{p-2}{2}$, for some $p > 2$. Then, for every n large enough,*

$$\mathbb{P} \left(\sup_{s,t \in \mathbb{R}} \left| \widehat{F}_{k,n}(s,t) - F_k(s,t) \right| > \varepsilon_n \right) \leq \frac{2^p t_n^2 D}{\varepsilon_n^p (n-k)^{p/2}},$$

with D defined as in Lemma 2.2.

Proof: From Lemma 2.3 and taking into account that $\varepsilon_n t_n \rightarrow +\infty$ we obtain, for every n large enough,

$$\begin{aligned} \mathbb{P}(D_{n,k} > \varepsilon_n) &\leq \mathbb{P} \left(D_{n,k}^* + \frac{2}{t_n} > \varepsilon_n \right) \\ &\leq \mathbb{P} \left(D_{n,k}^* > \frac{\varepsilon_n}{2} \right) + \mathbb{P} \left(\frac{2}{t_n} > \frac{\varepsilon_n}{2} \right) \\ &\leq \sum_{i,j=1,\dots,t_n} \mathbb{P} \left(\left| \widehat{F}_{k,n}(x_{n,i}, x_{n,j}) - F_k(x_{n,i}, x_{n,j}) \right| > \frac{\varepsilon_n}{2} \right) \\ &\leq t_n^2 \max_{i,j=1,\dots,t_n} \mathbb{P} \left(\left| \widehat{F}_{k,n}(x_{n,i}, x_{n,j}) - F_k(x_{n,i}, x_{n,j}) \right| > \frac{\varepsilon_n}{2} \right). \end{aligned}$$

Now, apply Lemma 2.2 to complete the proof. ■

3. Uniform strong convergence rates for $\widehat{F}_{k,n}$

Using Lemma 2.4 of the last section we will now obtain uniform strong convergence rates for the estimator $\widehat{F}_{k,n}$. In this section the letter C stands for a positive constant, which may take different values at each appearance. In each case the value of the constant is independent of n , but may depend on k and p .

Lemma 3.1. *Let $k \in \mathbb{N}_0$ be fixed. Suppose (S1) holds and (S2) is satisfied with $\theta = \frac{p-2}{2}$, for some $p > 2$. Then we have, for every $0 < \delta < \frac{p-2}{2}$,*

$$\sup_{s,t \in \mathbb{R}} \left| \widehat{F}_{k,n}(s,t) - F_k(s,t) \right| = O \left((\log n)^{\frac{2}{p+2}} n^{-\frac{p-2-2\delta}{2p+4}} \right) \quad a.s..$$

Proof: Fix $0 < \delta < \frac{p-2}{2}$ and put $t_n = \frac{\log n}{\varepsilon_n}$ in order to have $\varepsilon_n t_n \rightarrow +\infty$. Now, choosing $\varepsilon_n = (\log n)^{\frac{2}{p+2}} n^{-\frac{p-2-2\delta}{2p+4}}$, we will obtain from Lemma 2.4, for n large enough,

$$\mathbb{P} \left(\sup_{s,t \in \mathbb{R}} \left| \widehat{F}_{k,n}(s,t) - F_k(s,t) \right| > \varepsilon_n \right) \leq C \frac{(\log n)^2}{\varepsilon_n^{p+2} (n-k)^{p/2}} \leq C n^{-(1+\delta)}.$$

The sequence on the right-hand side above being summable, the result follows by the Borel-Cantelli Lemma. \blacksquare

Note that, $\frac{p-2-2\delta}{2p+4}$ approaches $1/2$ as p grows to ∞ , so the convergence rate established in the previous lemma can be arbitrarily close to $n^{-1/2}$, if a sufficiently large p can be chosen. As stated in the next theorem, this is always possible under assumption (G), but not under (P). In fact, with polynomially decreasing covariances, in order to have a convergence rate close to $n^{-1/2}$, we need to impose a further assumption on the covariances, namely, that this polynomial decrease is fast enough. This leads to large values of the exponent appearing in (P).

Theorem 3.2. *Let $k \in \mathbb{N}$ be fixed and suppose (S1) holds.*

a) *Under (G) we have, for every $0 < \gamma < 1/2$,*

$$\sup_{s,t \in \mathbb{R}} \left| \widehat{F}_{k,n}(s,t) - F_k(s,t) \right| = O(n^{-\gamma}) \quad a.s..$$

b) *Under (P) we have, for every $0 < \gamma < \frac{1}{2} - \frac{3}{a+3}$,*

$$\sup_{s,t \in \mathbb{R}} \left| \widehat{F}_{k,n}(s,t) - F_k(s,t) \right| = O \left((\log n)^{\frac{3}{3+a}} n^{-\gamma} \right) \quad a.s..$$

Proof: To prove a), fix $0 < \gamma < 1/2$. Now, choose $p > 2$ and $0 < \delta < \frac{p}{2} - 1$ so that $\frac{p-2-2\delta}{2p+4} > \gamma$. As already mentioned in Section 1, under (G) the assumption (S2) is satisfied regardless of the value of θ . In particular (S2) is satisfied for $\theta = \frac{p-2}{2}$. From Lemma 3.1, it follows that

$$\sup_{s,t \in \mathbb{R}} \left| \widehat{F}_{k,n}(s,t) - F_k(s,t) \right| \leq C (\log n)^{\frac{2}{p+2}} n^{-\frac{p-2-2\delta}{2p+4}} \leq C n^{-\gamma} \quad a.s.,$$

proving part *a*).

Under (P), as remarked in Section 1, assumption (S2) holds if $\theta \leq a/3 - 1$. According to Lemma 3.1, to obtain the best possible convergence rate, p must be chosen as large as possible. As $\theta = \frac{p-2}{2} \leq \frac{a}{3} - 1$, it follows that we must choose $p = 2a/3$. Then, for any fixed $\gamma \in (0, \frac{1}{2} - \frac{3}{a+3})$, part *b*) of the theorem follows directly from Lemma 3.1, replacing p by $2a/3$ and setting $\delta = \frac{a}{3} - 1 - 2\gamma\frac{a+3}{3}$. ■

Note that with $k = 0$ and $s = t$ the estimator $\widehat{F}_{k,n}(s, t)$ reduces to the one-dimensional empirical distribution function $\widehat{F}_n(s)$. So, the convergence rates of the previous theorem apply also to \widehat{F}_n . However, under (P) it is possible to obtain a slightly faster convergence rate for \widehat{F}_n . In fact, under the conditions of Lemma 2.4, with $k = 0$, we would obtain, for every n large enough,

$$\mathbb{P} \left(\sup_{s \in \mathbb{R}} \left| \widehat{F}_n(s) - F(s) \right| > \varepsilon_n \right) \leq \frac{2^p t_n D}{\varepsilon_n^p n^{p/2}}.$$

Then, following the arguments of the proofs of Lemma 3.1 and Theorem 3.2, we would find that, for every $0 < \gamma < \frac{1}{2} - \frac{9}{2(2a+3)}$,

$$\sup_{s \in \mathbb{R}} \left| \widehat{F}_n(s) - F(s) \right| = O \left((\log n)^{\frac{3}{3+2a}} n^{-\gamma} \right) \quad a.s..$$

This rate is somewhat faster than the rate given in part *b*) of the previous theorem.

We note also that the convergence rate for the case of geometrically decreasing covariances is arbitrarily near the optimal rate for \widehat{F}_n , in the independent setting. In fact, for independent samples, the Law of the Iterated Logarithm implies that the best possible convergence rate for the one-dimensional empirical distribution function is $O \left(\left(\frac{\log \log n}{n} \right)^{1/2} \right)$, which is just slightly faster than the rate given in the previous theorem for the case of geometrically decreasing covariances.

The next theorem is the analogue of Theorem 3.2 for the estimator $\widehat{\varphi}_{k,n}$.

Theorem 3.3. *Let $k \in \mathbb{N}$ be fixed and suppose (S1) holds.*

a) *Under (G) we have, for every $0 < \gamma < 1/2$,*

$$\sup_{s, t \in \mathbb{R}} \left| \widehat{\varphi}_{k,n}(s, t) - \varphi_k(s, t) \right| = O \left(n^{-\gamma} \right) \quad a.s..$$

b) Under (P) we have, for every $0 < \gamma < \frac{1}{2} - \frac{3}{a+3}$,

$$\sup_{s,t \in \mathbb{R}} |\widehat{\varphi}_{k,n}(s,t) - \varphi_k(s,t)| = O\left((\log n)^{\frac{3}{3+a}} n^{-\gamma}\right) \quad a.s..$$

Proof: As

$$\begin{aligned} & \sup_{s,t \in \mathbb{R}} |\widehat{\varphi}_{k,n}(s,t) - \varphi_k(s,t)| \leq \\ & \leq \sup_{s,t \in \mathbb{R}} \left| \widehat{F}_{k,n}(s,t) - F_k(s,t) \right| + \sup_{s,t \in \mathbb{R}} \left| F(s)F(t) - \widehat{F}_n(s)\widehat{F}_n(t) \right| \\ & \leq \sup_{s,t \in \mathbb{R}} \left| \widehat{F}_{k,n}(s,t) - F_k(s,t) \right| + \sup_{s,t \in \mathbb{R}} F(s) \left| F(t) - \widehat{F}_n(t) \right| \\ & \quad + \sup_{s,t \in \mathbb{R}} \widehat{F}_n(t) \left| F(s) - \widehat{F}_n(s) \right| \\ & \leq \sup_{s,t \in \mathbb{R}} \left| \widehat{F}_{k,n}(s,t) - F_k(s,t) \right| + 2 \sup_{s \in \mathbb{R}} \left| F(s) - \widehat{F}_n(s) \right|, \end{aligned}$$

the result follows immediately from Theorem 3.2. ■

4. Uniform strong convergence rates for $\widehat{\Gamma}_n$

In this section we will derive uniform strong convergence rates for the estimators of the sum $\sum_{k=1}^{\infty} \varphi_k(s,t)$ and of the covariance function $\Gamma(s,t)$. Analogously as in the previous section, C stands for a generic positive constant, but now independent of k and n (it may depend only on p).

Lemma 4.1. *Suppose (S1) holds and (S2) is satisfied with $\theta = \frac{p-2}{2}$, for some $p > 2$. Then, for each $0 < \delta < \frac{p-2}{2}$, if $a_n = n^{\frac{p-2-2\delta}{p^2+3p}}$ we have*

$$\sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} \widehat{\varphi}_{k,n}(s,t) - \sum_{k=1}^{\infty} \varphi_k(s,t) \right| = O\left((\log n)^{\frac{2}{p+2}} n^{-\frac{p^2-p(4+2\delta)+4(1+\delta)}{2(p^2+3p)}}\right) \quad a.s..$$

Proof: Let $0 < \delta < \frac{p-2}{2}$ and take $\varepsilon_n = (\log n)^{\frac{2}{2+p}} n^{-\frac{p^2-p(4+2\delta)+4(1+\delta)}{2(p^2+3p)}}$ and $t_n = \frac{a_n}{\varepsilon_n} \log n$. Now, write

$$\begin{aligned} & \mathbb{P} \left(\sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} (\widehat{F}_{k,n}(s,t) - F_k(s,t)) \right| > \varepsilon_n \right) \\ & \leq \sum_{k=1}^{a_n} \mathbb{P} \left(\sup_{s,t \in \mathbb{R}} \left| \widehat{F}_{k,n}(s,t) - F_k(s,t) \right| > \frac{\varepsilon_n}{a_n} \right). \end{aligned} \quad (11)$$

Note that, as $0 < \delta < \frac{p-2}{2}$, we have $\frac{p^2-p(4+2\delta)+4(1+\delta)}{2(p^2+3p)} > 0$ and $\frac{p-2-2\delta}{p^2+3p} > 0$, so that $\varepsilon_n \rightarrow 0$, $a_n \rightarrow +\infty$, $t_n \rightarrow +\infty$ and $\frac{\varepsilon_n}{a_n} t_n \rightarrow \infty$. Also, as $\frac{p-2-2\delta}{p^2+3p} < 1$, $\frac{a_n}{n} \rightarrow 0$.

From (11), applying Lemma 2.4 with $\frac{\varepsilon_n}{a_n}$ replacing ε_n , we conclude that there exists a constant $K = K(p)$ such that, for all n large enough,

$$\begin{aligned} \mathbb{P} \left(\sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} (\widehat{F}_{k,n}(s,t) - F_k(s,t)) \right| > \varepsilon_n \right) \\ \leq \sum_{k=1}^{a_n} K \left(1 + (10B_1 u(0))^{p/2} + c_k \right) \frac{2^p t_n^2 a_n^p}{\varepsilon_n^p (n-k)^{p/2}}, \end{aligned} \quad (12)$$

where $c_k = B_1 \max \{4C_0(k+1)^\theta, 3C_0 + 2u(0)k^\theta\}$.

Since $k \leq a_n$, it follows that $c_k \leq B_1 \max \{4C_0(a_n+1)^\theta, 3C_0 + 2u(0)a_n^\theta\} \leq C a_n^\theta$, so that from (12) we obtain, for n large enough,

$$\begin{aligned} \mathbb{P} \left(\sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} (\widehat{F}_{k,n}(s,t) - F_k(s,t)) \right| > \varepsilon_n \right) \\ \leq \sum_{k=1}^{a_n} K \left(1 + (10B_1 u(0))^{p/2} + C a_n^\theta \right) \frac{2^p t_n^2 a_n^p}{\varepsilon_n^p (n-k)^{p/2}} \\ \leq \sum_{k=1}^{a_n} C a_n^\theta \frac{t_n^2 a_n^p}{\varepsilon_n^p (n-k)^{p/2}} \\ \leq C \frac{t_n^2 a_n^{3p/2}}{\varepsilon_n^p (n-a_n)^{p/2}}, \end{aligned} \quad (13)$$

remembering that $\theta = \frac{p-2}{2}$.

By elementary manipulations it is easy to check that

$$\frac{p^2 - p(4+2\delta) + 4(1+\delta)}{2(p^2+3p)} = \frac{p-2-2\delta}{p^2+3p} \cdot \frac{3p+4}{2(p+2)} - \frac{p-2-2\delta}{2(p+2)}, \quad (14)$$

so, we may write $\varepsilon_n = (\log n)^{\frac{2}{p+2}} a_n^{\frac{3p+4}{2(p+2)}} n^{-\frac{p-2-2\delta}{2(p+2)}}$. Inserting this and the choice made for t_n on the right-hand side of (13) it follows that

$$\mathbb{P} \left(\sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} (\widehat{F}_{k,n}(s,t) - F_k(s,t)) \right| > \varepsilon_n \right) \leq C \frac{n^{\frac{p-2-2\delta}{2}}}{(n-a_n)^{p/2}}.$$

As $\frac{a_n}{n} \longrightarrow 0$, we have $\frac{n^{\frac{p-2-2\delta}{2}}}{(n-a_n)^{p/2}} \sim n^{-(1+\delta)}$, thus the sequence on the upper bound above is summable. Then, from the Borel-Cantelli Lemma it follows that

$$\sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} (\widehat{F}_{k,n}(s,t) - F_k(s,t)) \right| = O \left((\log n)^{\frac{2}{p+2}} n^{-\frac{p^2-p(4+2\delta)+4(1+\delta)}{2(p^2+3p)}} \right) \quad a.s.. \quad (15)$$

Now, we may write

$$\begin{aligned} \left| \sum_{k=1}^{a_n} \widehat{\varphi}_{k,n}(s,t) - \sum_{k=1}^{\infty} \varphi_k(s,t) \right| &\leq \left| \sum_{k=1}^{a_n} (\widehat{\varphi}_{k,n}(s,t) - \varphi_k(s,t)) \right| + \left| \sum_{k=a_n+1}^{\infty} \varphi_k(s,t) \right| \\ &\leq \left| \sum_{k=1}^{a_n} (\widehat{F}_{k,n}(s,t) - F_k(s,t)) \right| + a_n \left| F(t) - \widehat{F}_n(t) \right| + a_n \left| F(s) - \widehat{F}_n(s) \right| \\ &\quad + \left| \sum_{k=a_n+1}^{\infty} \varphi_k(s,t) \right|. \end{aligned}$$

Thus,

$$\begin{aligned} \sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} \widehat{\varphi}_{k,n}(s,t) - \sum_{k=1}^{\infty} \varphi_k(s,t) \right| &\leq \\ &\leq \sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} (\widehat{F}_{k,n}(s,t) - F_k(s,t)) \right| + 2 a_n \sup_{s,t \in \mathbb{R}} \left| F(t) - \widehat{F}_n(t) \right| \quad (16) \\ &\quad + \sup_{s,t \in \mathbb{R}} \left| \sum_{k=a_n+1}^{\infty} \varphi_k(s,t) \right|. \end{aligned}$$

The convergence rate of the first term on the right-hand side above is given in (15). From Lemma 3.1 the second term is almost surely $O \left(a_n (\log n)^{\frac{2}{p+2}} n^{-\frac{p-2-2\delta}{2p+4}} \right)$. Since $\frac{3p+4}{2p+4} > 1$ and taking into account (14), we have

$$a_n (\log n)^{\frac{2}{p+2}} n^{-\frac{p-2-2\delta}{2p+4}} < a_n^{\frac{3p+4}{2p+4}} (\log n)^{\frac{2}{p+2}} n^{-\frac{p-2-2\delta}{2p+4}} = (\log n)^{\frac{2}{p+2}} n^{-\frac{p^2-p(4+2\delta)+4(1+\delta)}{2(p^2+3p)}}.$$

Thus,

$$a_n \sup_{s,t \in \mathbb{R}} \left| F(t) - \widehat{F}_n(t) \right| = O \left((\log n)^{\frac{2}{p+2}} n^{-\frac{p^2-p(4+2\delta)+4(1+\delta)}{2(p^2+3p)}} \right) \quad a.s..$$

Finally, we will check that the third term on the right-hand side of (16) is of the same order. According to (7), we have

$$\begin{aligned} \sup_{s,t \in \mathbb{R}} \left| \sum_{k=a_n+1}^{\infty} \varphi_k(s,t) \right| &= \sup_{s,t \in \mathbb{R}} \sum_{k=a_n+1}^{\infty} \text{Cov} \left(I_{(-\infty,s]}(X_1), I_{(-\infty,t]}(X_{k+1}) \right) \\ &\leq B_1 \sum_{k=a_n+1}^{\infty} \text{Cov}^{1/3}(X_1, X_{k+1}) \\ &= B_1 u(a_n) \leq C a_n^{-\frac{p-2}{2}}, \end{aligned}$$

since assumption (S2) is satisfied for $\theta = \frac{p-2}{2}$. Now, it is easy to check that

$$a_n^{-\frac{p-2}{2}} = n^{-\frac{p^2-p(4+2\delta)+4(1+\delta)}{2(p^2+3p)}},$$

hence,

$$\sup_{s,t \in \mathbb{R}} \left| \sum_{k=a_n+1}^{\infty} \varphi_k(s,t) \right| = O \left(n^{-\frac{p^2-p(4+2\delta)+4(1+\delta)}{2(p^2+3p)}} \right),$$

so the proof is concluded. \blacksquare

It is worth noticing that choosing, in the previous lemma, $a_n = (\log n)^{-\frac{4}{p^2+3p}} n^{\frac{p-2-2\delta}{p^2+3p}}$, we would have obtained the slightly improved convergence rate,

$$\sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} \widehat{\varphi}_{k,n}(s,t) - \sum_{k=1}^{\infty} \varphi_k(s,t) \right| = O \left((\log n)^{\frac{2(p-2)}{p^2+3p}} n^{-\frac{p^2-p(4+2\delta)+4(1+\delta)}{2(p^2+3p)}} \right) \quad a.s..$$

As the gain in the convergence rate is marginal, we will continue with the choice for a_n as in the lemma, just remarking the slightly improved version at the end.

Theorem 4.2. *Suppose (S1) holds.*

a) *Under (G) we have, for every $0 < \gamma < 1/2$,*

$$\sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} \widehat{\varphi}_{k,n}(s,t) - \sum_{k=1}^{\infty} \varphi_k(s,t) \right| = O(n^{-\gamma}) \quad a.s.,$$

if $a_n = n^{\frac{p-2-2\delta}{p^2+3p}}$, with $\delta > 0$ and $p > 2$ chosen such that $\frac{p^2-p(4+2\delta)+4(1+\delta)}{2(p^2+3p)} > \gamma$.

b) Under (P) we have, for every $0 < \gamma < \frac{1}{2} - \frac{21a-18}{2a(2a+9)}$,

$$\sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} \widehat{\varphi}_{k,n}(s,t) - \sum_{k=1}^{\infty} \varphi_k(s,t) \right| = O\left((\log n)^{\frac{3}{3+a}} n^{-\gamma}\right) \quad a.s.,$$

if $a_n = n^{\frac{3}{a-3}\gamma}$.

Proof: Follow the arguments of the proof of Theorem 3.2, invoking Lemma 4.1 instead of Lemma 3.1 (for the proof of part b) take $\delta = \frac{a-3}{3} - \gamma \frac{a(2a+9)}{3(a-3)}$. \blacksquare

The next result states the convergence rates for the $\widehat{\Gamma}_n$.

Theorem 4.3. *Suppose (S1) holds.*

a) Under (G) we have, for every $0 < \gamma < 1/2$,

$$\sup_{s,t \in \mathbb{R}} \left| \widehat{\Gamma}_n(s,t) - \Gamma(s,t) \right| = O(n^{-\gamma}) \quad a.s.,$$

if $a_n = n^{\frac{p-2-2\delta}{p^2+3p}}$, with $\delta > 0$ and $p > 2$ chosen such that $\frac{p^2-p(4+2\delta)+4(1+\delta)}{2(p^2+3p)} > \gamma$.

b) Under (P) we have, for every $0 < \gamma < \frac{1}{2} - \frac{21a-18}{2a(2a+9)}$,

$$\sup_{s,t \in \mathbb{R}} \left| \widehat{\Gamma}_n(s,t) - \Gamma(s,t) \right| = O\left((\log n)^{\frac{3}{3+a}} n^{-\gamma}\right) \quad a.s.,$$

if $a_n = n^{\frac{3}{a-3}\gamma}$.

Proof: First write

$$\begin{aligned} & \sup_{s,t \in \mathbb{R}} \left| \widehat{\Gamma}_n(s,t) - \Gamma(s,t) \right| \\ & \leq \sup_{s,t \in \mathbb{N}} \left| \widehat{F}_n(s \wedge t) - F(s \wedge t) \right| + 2 \sup_{s \in \mathbb{R}} \left| \widehat{F}_n(s) - F(s) \right| + \\ & \quad + \sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} \widehat{\varphi}_{k,n}(s,t) - \sum_{k=1}^{\infty} \varphi_k(s,t) \right| \\ & \quad + \sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} \widehat{\varphi}_{k,n}(t,s) - \sum_{k=1}^{\infty} \varphi_k(t,s) \right|. \end{aligned} \tag{17}$$

Thus, under (G) the result follows directly from Theorems 3.2 and 4.2.

For the proof of part *b*), fix $\gamma \in \left(0, \frac{1}{2} - \frac{21a-18}{2a(2a+9)}\right)$. Since $\frac{21a-18}{2a(2a+9)} > \frac{3}{a+3}$, obviously $\gamma \in \left(0, \frac{1}{2} - \frac{3}{a+3}\right)$. It follows then from Theorem 3.2 that the two first terms of the right-hand side of (17) are almost surely $O\left((\log n)^{\frac{3}{3+a}} n^{-\gamma}\right)$. Finally, if $a_n = n^{\frac{3}{a-3}\gamma}$, by Theorem 4.2 the fourth and fifth terms are of the same order. ■

As mentioned earlier, choosing $a_n = (\log n)^{-\frac{4}{p^2+3p}} n^{\frac{p-2-2\delta}{p^2+3p}}$ we would obtain a slight improvement on our convergence rates, for the case of polynomially decreasing covariances. In fact, in the previous two theorems, with this choice for a_n , we would obtain the same convergence rate under (G), whereas under (P) (with p and δ as in the proof of Theorem 4.2), both $\sup_{s,t \in \mathbb{R}} \left| \sum_{k=1}^{a_n} \widehat{\varphi}_{k,n}(s,t) - \sum_{k=1}^{\infty} \varphi_k(s,t) \right|$ and $\sup_{s,t \in \mathbb{R}} \left| \widehat{\Gamma}_n(s,t) - \Gamma(s,t) \right|$ would be, almost surely,

$$O\left((\log n)^{\frac{6a-18}{2a^2+9a}} n^{-\gamma}\right) \quad a.s. ,$$

for any $0 < \gamma < \frac{1}{2} - \frac{21a-18}{2a(2a+9)}$.
