CONJUGATION SEMIGROUPS AND CONJUGATION
MONOIDS WITH CANCELLATION

ANA PAULA GARRÃO, NELSON MARTINS-FERREIRA, MARGARIDA RAPOSO
AND MANUELA SOBRAL

Abstract: We show that the category of conjugation semigroups with cancellation
is weakly Mal’tsev and give a characterization of all admissible diagrams there. In
the subcategory of conjugation monoids with cancellation we describe, for Schreier
split epimorphisms with codomain $B$ and kernel $X$, all morphisms $h : X \to B$
which induce a reflexive graph, an internal category or an internal groupoid there.
In this subcategory we prove that a relative version of the so-called “Smith is Huq”
condition for Schreier split epimorphisms holds as well as other relative conditions.

Keywords: Admissibility diagrams, weakly Mal’tsev category, conjugation semig-
roups, internal monoid, internal groupoid.

1. Introduction

In [11] the concept of weakly Mal’tsev category was introduced to provide
a simple axiomatic context where the internal categories and the internal
groupoids are particularly simple to describe, the established notion of Mal’tsev
category ([7]) being too restrictive for this purpose since there the two notions
coincide. Amongst the categories that are weakly Mal’tsev but not Mal’tsev
are the categories of distributive lattices ([14]) and the category of commut-
ative monoids with cancellation. In this paper we introduce another class of
examples of such categories, that includes the later, characterize there all the
admissible diagrams and describe some internal structures. The admissibility
of certain type of diagrams is used to go from local to global in a sense we
make precise below.

We introduce the category of conjugation semigroups which can be seen
as an abstraction of conjugation of complex numbers or of quaternions. A
conjugation semigroup \((S, \cdot, (\ ))\) is a semigroup \((S, \cdot)\) equipped with a unary operation \((\ )): S \rightarrow S\) satisfying the following identities: \(x\overline{x} = xx, x\overline{yy} = y\overline{yx},\) and \(x\overline{y} = \overline{y}\overline{x}\). The quasivariety of conjugation semigroups with cancellation is a weakly Mal’tsev category, that is not Mal’tsev, and we present there a characterization of all admissible diagrams in the sense of [12].

In the subcategory of conjugation monoids with cancellation we describe for Schreier split epimorphisms with codomain \(B\) and kernel \(X\) (a notion first introduced in [16] for monoids with operations),

\[
\begin{array}{c}
X \\ \xrightarrow{h} \\ A \\ \xrightarrow{f} \\ B
\end{array}
\]

all morphisms \(h: X \rightarrow B\) which induce a reflexive graph, an internal category or an internal groupoid. That is, all morphisms \(h: X \rightarrow B\) that induce a morphism \(\tilde{h}: A \rightarrow B\), with \(\tilde{h}k = h\), such that

\[
\begin{array}{c}
A \\ \xrightarrow{f} \\ B
\end{array}
\]

gives rise to a reflexive graph, an internal category or an internal groupoid.

We show that a relative version of the so-called “Smith is Huq” condition holds for Schreier split epimorphisms in the category of conjugation monoids with cancellation as well as other relative conditions.

Throughout, for simplicity of exposition, we will use additive notation for monoids and semigroups, though we do not assume commutativity.

2. Preliminaries

We recall here definitions and basic properties that will be used throughout.

In a category with pullbacks of split epimorphisms along split epimorphisms we consider the following diagram

\[
\begin{array}{ccc}
A \times_{B} C & \xrightarrow{e_{2}} & C \\
\downarrow{\pi_{1}} & & \downarrow{g} \\
A & \xleftarrow{r} & B
\end{array}
\]

\[
\begin{array}{ccc}
A \times_{B} C & \xrightarrow{e_{2}} & C \\
\downarrow{\pi_{1}} & & \downarrow{g} \\
A & \xleftarrow{r} & B
\end{array}
\]

\[e_{1} \quad g \quad s\]
where $fr = 1_B = gs$, $(\pi_1, \pi_2)$ is the pullback of $(f, g)$ and $e_1 = <1_A, sf>$, $e_2 = <rg, 1_C>$ are the morphisms induced by the universal property of the pullback. Then $e_1 r = e_2 s$.

Any diagram

\begin{equation}
\begin{array}{ccc}
A & \xrightarrow{f} & B & \xrightarrow{g} & C \\
\downarrow{r} & \downarrow{\alpha} & \downarrow{\beta} & \downarrow{\gamma} \\
D & \xleftarrow{\phi} & C
\end{array}
\end{equation}

with $fr = 1_B = gs$ and $\alpha r = \beta = \gamma s$ will be called an admissibility diagram. It induces a diagram

\begin{equation}
\begin{array}{ccc}
A \times_B C & \xrightarrow{e_2} & B & \xrightarrow{g} & D \\
\downarrow{\pi_1} & \downarrow{\pi_2} & \downarrow{\beta} & \downarrow{\gamma} \\
C & \xleftarrow{\phi} & B
\end{array}
\end{equation}

and the existence of a unique morphism $\varphi: A \times_B C \longrightarrow D$ such that $\varphi e_1 = \alpha$ and $\varphi e_2 = \gamma$ is a way to describe relevant situations and results in categorical algebra as we mention next.

**Definition 2.1.** The triple $(\alpha, \beta, \gamma)$ is admissible with respect to $(f, r, g, s)$ if there exists a unique morphism $\varphi: A \times_B C \longrightarrow D$ such that $\varphi e_1 = \alpha$ and $\varphi e_2 = \gamma$. Then we say that the diagram (1) is admissible.

The unicity of $\varphi$ is fundamental and it is achieved in the context of weakly Mal’tsev categories, a notion introduced in [11]. See also [12].

**Definition 2.2.** A finitely complete category $C$ is weakly Mal’tsev if the morphisms $e_1 = <1_A, sf>$ and $e_2 = <rg, 1_C>$ are jointly epimorphic.

In a weakly Mal’tsev category, the morphism $\varphi$ is unique and so the admissibility of diagram (1) is a condition and not an additional structure.

We recall that a finitely complete category is Mal’tsev if $(e_1, e_2)$ is jointly strongly pair ([2]). Hence, all Mal’tsev categories are weakly Mal’tsev but the converse is false. For example, the category of distributive lattices is a weakly Mal’tsev category which is not Mal’tsev ([14]).
In a weakly Mal’tsev category $\mathcal{C}$ the admissibility of diagrams (1) describe several conditions and properties of $\mathcal{C}$. For example, the reflexive graph

$$C_1 \xrightarrow{\begin{smallmatrix} d \\ e \end{smallmatrix}} C_0$$

is an internal category in $\mathcal{C}$ if and only if the diagram

$$\begin{array}{ccc}
C_1 & \xrightarrow{d} & C_0 \\
\downarrow{e} & & \downarrow{e} \\
C_1 & & C_1
\end{array}$$

is admissible. And an internal category in $\mathcal{C}$

$$C_2 = C_1 \times_{C_0} C_1 \xrightarrow{m} C_1 \xrightarrow{\begin{smallmatrix} d \\ c \end{smallmatrix}} C_0$$

is a groupoid if and only if the diagram

$$\begin{array}{ccc}
C_2 & \xrightarrow{m} & C_1 \\
\downarrow{<1_{C_1},ed>} & & \downarrow{<ee,1_{C_1}>} \\
C_1 & & C_1
\end{array}$$

is admissible ([12]).

A pair $(R, S)$ of equivalence relations on an object $X$

$$\begin{array}{ccc}
R & \xleftarrow{i_R} & X & \xrightarrow{i_S} & S \\
\xrightarrow{r_1} & & \xrightarrow{s_1} & & \xrightarrow{s_2} \xrightarrow{r_2}
\end{array}$$

commute in the sense of Smith-Pedicchio [20], [19] if and only if the diagram
is admissible, i.e. if and only if there exists a morphism \( \varphi : R \times_X S \to X \) such that \( \varphi < 1_R, i_S r_2 >= r_1 \) and \( \varphi < i_r s_1, 1_S >= s_2 \).

A cospan

\[
\begin{array}{ccc}
K & \xrightarrow{k} & X & \xleftarrow{l} & L \\
\downarrow & & \downarrow & & \\
X & & & & \\
\end{array}
\]

of morphisms in a pointed category commute in the sense of Huq ([8]) if and only if the diagram

\[
\begin{array}{ccc}
K & \xrightarrow{0} & L \\
\downarrow & & \downarrow \\
X & & X \\
\end{array}
\]

is admissible. This means the existence of a unique \( \varphi : K \times L \to X \) such that \( \varphi < 1,0 >= k \) and \( \varphi < 0,1 >= l \).

In [21], Tim Van der Linden observed that this very flexible condition of admissibility is indeed a commutativity condition.

It is well-known that in groups there is an equivalence between the category of split epimorphisms with codomain \( B \) and kernel \( X \) and group actions of \( B \) on \( X \), that is group homomorphisms \( \varphi : B \to Aut(X) \).

This is not true in the category of monoids. There, the classical notion of monoid action, that is a monoid homomorphism \( \varphi : B \to End(X) \), corresponds to a special class of split epimorphisms called Schreier split epimorphisms introduced in [16], in the more general context of monoids with operations, and studied in detail in [5] and [4].

**Definition 2.3.** A Schreier split epimorphism in the category \( Mon \) of monoids is a split epimorphism \( (f,r) \), \( fr = 1_B \), with kernel \( X \), for which there exists a unique set-theoretical map \( q : A \to X \), called the Schreier retraction,
such that, for every \( a \in A \), \( a = kq(a) + rf(a) \).

Equivalently, the following conditions should be satisfied

(i) \( a = kq(a) + rf(a) \) and
(ii) \( x = q(k(x) + r(b)) \),

for all \( a \in A \), \( x \in X \) and \( b \in B \), since (ii) gives the unicity of the set map \( q \).

In the following proposition (proved in [4]) we list consequences of the definition that will be used in the sequel.

**Proposition 2.4.** Given a Schreier split epimorphism in the category \( \text{Mon} \) of monoids

\[
\begin{array}{c}
X \xleftarrow{k} A \xrightarrow{f} B
\end{array}
\]

we have that, for \( a, a' \in A \), \( x \in X \) and \( b \in B \),

(a) \( qk = 1_X \);
(b) \( qr = 0 \);
(c) \( q(0) = 0 \);
(d) \( kq(r(b) + k(x)) + r(b) = r(b) + k(x) \);
(e) \( q(a + a') = q(a) + q(rf(a) + q(a')) \);
(f) the sequence is exact, that is \( X = \text{ker} f \) and \( f = \text{coker} k \), and so we speak of Schreier extension.

To the Schreier extension above corresponds an action \( \varphi : B \rightarrow \text{End}(X) \) defined by

\[
\varphi(b)(x) = q(r(b) + k(x))
\]

that we will denote by \( b \cdot x \). Then, for example condition (d) can be written as

\[
k(b \cdot x) + r(b) = r(b) + k(x).
\]

3. Conjugation semigroups with cancellation

**Definition 3.1.** A conjugation semigroup \((S, +, (\overline{\cdot}))\) is a semigroup \((S, +)\) equipped with a unary operation \((\overline{\cdot}) : S \rightarrow S\) satisfying the following identities:

(1) \( \overline{x + x} = x + \overline{x} \)
(2) \( x + \overline{y} + y = y + \overline{y} + x \)
(3) \( (x + y) = \overline{y} + \overline{x} \)

Examples are groups with \( \overline{x} = x^{-1} \), commutative monoids with \( \overline{x} = 1 \) and commutative semigroups with \( \overline{x} = x \). The main examples that illustrate our intuition behind the notion of conjugation semigroups are sets of non-zero complex numbers and non-zero quaternions with usual multiplication and conjugation.

The quasivariety \( \mathcal{S} \) of conjugation semigroups satisfying the implications

(4) \( x + a + a = y + a + a \Rightarrow x = y \)

is a weakly Mal’tsev category. Indeed, this subvariety has a ternary operation

\[
p(x, y, z) = x + \overline{y} + z
\]

satisfying the identity

\[
p(x, y, y) = p(y, y, x)
\]

and the quasi-identity

\[
p(x, y, y) = p(x', y, y) \Rightarrow x = x'
\]

and so it is weakly Mal’tsev as proved in [14].

It is easy to prove that, in presence of (1)-(3), condition (4) is equivalent to cancellation. So, throughout, \( \mathcal{S} \) will denote the category of conjugation semigroups with cancellation.

Remark 3.2. From the definition of conjugation semigroup it follows that:

(i) \( (x + y) + (x + y) = \overline{y} + y + x + \overline{x} \) because
\[
(x + y) + (x + y) = \overline{y} + \overline{x} + x + y = \overline{y} + x + \overline{x} + y = \overline{y} + y + x + \overline{x} = \overline{y} + y + x + \overline{x}.
\]
(ii) \( x + y + \overline{y} = \overline{y} + y + x \)

that we will use in the sequel.

The following are examples of conjugation semigroups with cancellation that are neither groups nor monoids:

1. \( S = \{ u \in \mathbb{R} | 0 < |u| < 1 \} \) with usual product and \( \overline{u} = u \).
2. \( S = \{ z \in \mathbb{C} | 0 < ||z|| < 1 \} \) with usual product and conjugation.
3. \( S = \{ q \in \mathbb{H} | 0 < ||q|| < 1 \} \) with quaternion product and conjugation.
4. Admissibility in $S$

In the weakly Mal’tsev category $S$, of conjugation semigroups with cancellation and semigroup homomorphisms preserving conjugation, we are going to give a characterization of all admissible diagrams.

Theorem 4.1. A diagram

$$
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\alpha & \downarrow & \beta \\
& \downarrow & \\
D & \xleftarrow{g} & C
\end{array}
$$

in $S$, with $fr = qs = 1_B$ and $\alpha r = \beta = \gamma s$, is admissible if and only if the following conditions hold:

(Ad1) the equation

$$x + \beta(b) + \beta(b) = \alpha(a) + \beta(b) + \gamma(c)$$

has a unique solution for all $a \in A$ and $c \in C$ such that $f(a) = g(c) = b \in B$.

(Ad2) the equation

$$\alpha(a_1 + a_2) + \beta(b_1 + b_2) + \gamma(c_1 + c_2) = \alpha(a_1) + \beta(b_1) + \gamma(c_1) + \alpha(a_2) + \beta(b_2) + \gamma(c_2)$$

is satisfied for $a_1, a_2 \in A$ and $c_1, c_2 \in C$ such that $f(a_1) = g(c_1) = b_1 \in B$ and $f(a_2) = g(c_2) = b_2 \in B$.

Proof: If there exists a morphism $\varphi: A \times_B C \to D$ in $S$ such that $\varphi e_1 = \alpha$ and $\varphi e_2 = \gamma$ then

$$\alpha(a) = \varphi e_1(a) = \varphi(a, sf(a)) = \varphi(a, s(b))$$

$$\gamma(c) = \varphi e_2(c) = \varphi(rq(c), c) = \varphi(r(b), c)$$

and $\beta(b) = \varphi(r(b), s(b))$, for $f(a) = g(c) = b$.

Then $\varphi(a, c)$ is a solution of (Ad1):

$$\varphi(a, c) + \beta(b) + \beta(b) = \varphi(a, c) + \varphi(r(b), s(b)) + \varphi(r(b), s(b))$$

$$= \varphi(a, c) + \varphi(r(b), s(b)) + \varphi(r(b), s(b))$$

$$= \varphi(a + r(b) + r(b), s(b)) = \varphi(a + r(b) + r(b), s(b) + s(b) + c)$$

$$= \varphi(a, s(b)) + \varphi(r(b), s(b)) + \varphi(r(b), c) = \alpha(a) + \beta(b) + \gamma(c)$$

because $\varphi$ is a morphism of $S$ and by 3.1 (2).

To prove (Ad2) we use the previous result and 3.2.
\[ \alpha(a_1 + a_2) + \beta(b_1 + b_2) + \gamma(c_1 + c_2) = \\
= \varphi(a_1 + a_2, c_1 + c_2) + \beta(b_1 + b_2) + \beta(b_1 + b_2) \\
= \varphi(a_1, c_1) + \varphi(a_2, c_2) + (\beta(b_1) + \beta(b_2)) + \beta(b_1) + \beta(b_2) \\
= \varphi(a_1, c_1) + \varphi(a_2, c_2) + \beta(b_2) + \beta(b_2) + \beta(b_1) + \beta(b_1) \\
= \varphi(a_1, c_1) + \beta(b_1) + \beta(b_1) + \varphi(a_2, c_2) + \beta(b_2) + \beta(b_2) \\
= \alpha(a_1) + \beta(b_1) + \gamma(c_1) + \alpha(a_2) + \beta(b_2) + \gamma(c_2). \]

Conversely, let us assume that (Ad1) and (Ad2) hold. Then we can define \( \varphi(a, c) = x \) where \( x \) is the solution of the equation (Ad1), such that \( \varphi e_1 = \alpha \) and \( \varphi e_2 = \gamma \). Indeed, \( \varphi e_1(a) = \alpha(a) \), since \( \varphi e_1(a) = \varphi(a, sf(a)) \) satisfies the equation (Ad1):

\[ \varphi(a, sf(a)) + \beta f(a) + \beta f(a) = \alpha(a) + \beta f(a) + \gamma sf(a) = \]
\[ = \alpha(a) + \beta f(a) + \beta f(a). \]

By cancellation, we have that \( \varphi(a, sf(a)) = \varphi e_1(a) = \alpha(a) \).

Analogously,

\[ \varphi(rg(c), c) + \beta g(c) + \beta g(c) = a r g(c) + \beta g(c) + \gamma(c) = \]
\[ = \beta g(c) + \beta g(c) + \gamma(c) = \gamma(c) + \beta g(c) + \beta g(c). \]

So, \( \varphi e_2(c) = \varphi(rg(c), c) = \gamma(c) \).

It remains to prove that \( \varphi \) is a semigroup homomorphism that preserves conjugation:

\[ \varphi(a_1, c_1) + \varphi(a_2, c_2) + \beta(b_1 + b_2) + \beta(b_1 + b_2) = \]
\[ = \varphi(a_1, c_1) + \varphi(a_2, c_2) + \beta(b_1) + \beta(b_2) + \beta(b_1) + \beta(b_2) \\
= \varphi(a_1, c_1) + \beta(b_1) + \beta(b_1) + \varphi(a_2, c_2) + \beta(b_2) + \beta(b_2) \\
= \alpha(a_1) + \beta(b_1) + \gamma(c_1) + \alpha(a_2) + \beta(b_2) + \gamma(c_2) \\
= \varphi(a_1 + a_2, c_1 + c_2) + \beta(b_1 + b_2) + \beta(b_1 + b_2), \]

for \( f(a_1) = g(c_1) = b_1 \) and \( f(a_2) = g(c_2) = b_2 \).

Thus \( \varphi(a_1 + a_2, c_1 + c_2) = \varphi(a_1, c_1) + \varphi(a_2, c_2) \).

Now we have that

\[ \varphi(\bar{a}, \bar{c}) + \beta(\bar{b}) + \beta(\bar{b}) = \alpha(\bar{a}) + \beta(\bar{b}) + \gamma(\bar{c}), \]

but

\[ [\varphi(a, c)] + \beta(\bar{b}) + \beta(\bar{b}) = (\beta(b) + \beta(\bar{b}) + \varphi(a, c)) = (\varphi(a, c) + \beta(\bar{b}) + \beta(b)) = \]
\[ = (\alpha(a) + \beta(\bar{b}) + \gamma(c)) = \gamma(\bar{c}) + \beta(\bar{b}) + \alpha(\bar{a}), \]

being \( \alpha(a) + \beta(\bar{b}) + \gamma(c) = \gamma(c) + \beta(\bar{b}) + \alpha(a) \), for all \( a, b \) and \( c \) such that \( f(a) = b = g(c) \), that we prove next, and so \( \varphi(a, c) = \varphi(\bar{a}, \bar{c}) \).

Indeed,
\[
\alpha(a) + \beta(b) + \gamma(c) = \varphi(a, c) + \beta(b) + \gamma(c) = \\
= \varphi(a, c) + \varphi(r(b), s(b)) + \varphi(r(b), s(b)) \\
= \varphi(a + r(b) + r(b), c + s(b) + s(b)) \\
= \varphi(r(b) + r(b) + a, c + s(b) + s(b)) \\
= \varphi(r(b), c) + \varphi(r(b), s(b)) + \varphi(a, s(b)) \\
= \gamma(c) + \beta(b) + \alpha(a),
\]
and this concludes the proof. \(\square\)

5. Internal structures in \(\mathcal{M}\)

We are going to consider the category \(\mathcal{M}\) of conjugation monoids with cancellation and monoid homomorphisms that preserve conjugation. This subcategory of \(\mathcal{S}\) is weakly Mal’tsev. Also the characterization 4.1 is still valid for diagrams (1) in \(\mathcal{M}\). To prove that it is enough to show that if (Ad1) and (Ad2) hold then \(\varphi(0, 0) = 0\).

And this indeed is the case, since if

\[
\varphi(0, 0) + \beta(0) + \beta(0) = \alpha(0) + \beta(0) + \beta(0)
\]

in \(\mathcal{S}\) then

\[
\varphi(0, 0) + \beta(0) = 0 + \beta(0)
\]

because \(\alpha(0) = \beta(0) = 0\) and so, by cancellation \(\varphi(0, 0) = 0\).

Let \((f, r)\) be a Schreier split epimorphism in \(\mathcal{M}\)

\[
X \xrightarrow{q} A \xrightarrow{r} B
\]

we are going to investigate which \(\mathcal{M}\)-morphisms \(h : X \to B\) induce in \(\mathcal{M}\)

(i) an internal reflexive graph,
(ii) an internal category or
(iii) an internal groupoid,

in the sense we make precise below.

Lemma 5.1. Given a Schreier split epimorphism in \(\mathcal{M}\), the Schreier retraction satisfies the equality

\[
q(\bar{a}) = f(\bar{a}) \cdot \overline{q(a)}.
\]

Proof: We have that

\[
f(\bar{a}) \cdot q(a) = q(rf(\bar{a}) + kq(a)) = q(kq(a) + rf(\bar{a})) = q(\bar{a}).
\]
So, together with 2.4 (a)-(e), this describes the behaviour of the Schreier retraction in $\mathcal{M}$.

Given $h : X \to B$ and the Schreier split epimorphism $(f, r)$ in $\mathcal{M}$

\[
\begin{array}{c}
X \xrightarrow{q} A \xrightarrow{f} B \\
\end{array}
\]

when does $h$ induce a reflexive graph in $\mathcal{M}$? That is, when does it induce a $\mathcal{M}$-morphism $\tilde{h} : A \to B$ such that

$\tilde{hk} = h$ and $\tilde{hr} = 1_B$?

If such an $\tilde{h}$ exists, since it is a morphism in $\mathcal{M}$ and $a = kq(a) + rf(a)$, we have

1. $\tilde{h}(a) = \tilde{h}(kq(a) + rf(a)) = hq(a) + f(a)$;
2. $\tilde{h}(\overline{a}) = \overline{h(a)}$.

**Remark 5.2.** If $\tilde{h}$ exists it is defined by (1) and then (2) holds:

$\tilde{h}(\overline{a}) = \tilde{h}(kq(a) + rf(a)) = \tilde{h}(rf(\overline{a}) + k\overline{q(a)}) = f(\overline{a}) + h\overline{q(a)}$

and

$\overline{\tilde{h}(a)} = \overline{hq(a) + f(a)} = f(\overline{a}) + h\overline{q(a)}$.

**Proposition 5.3.** In the category $\mathcal{M}$, given a Schreier split epimorphism

\[
\begin{array}{c}
X \xrightarrow{q} A \xrightarrow{r} B \\
\end{array}
\]

a morphism $h : X \to B$ induces a reflexive graph

\[
\begin{array}{c}
A \xrightarrow{f} B \\
\end{array}
\]

if and only if it satisfies the condition

$(C1) \; h(b \cdot x) + b = b + h(x)$.

**Proof:** If there exists $\tilde{h}$, such that $\tilde{hk} = h$ and $\tilde{hr} = 1_B$ then, for $b = f(a)$ and $x = q(a)$, we have that
\[ b + h(x) = f(a) + hq(a) \]
\[ = \tilde{h}(rf(a) + kq(a)) \]
\[ = \tilde{h}(kq(rf(a) + kq(a)) + rf(rf(a) + kq(a))) \]
\[ = \tilde{h}kq(rf(a) + kq(a)) + \tilde{h}rf(a) \]
\[ = hq(rf(a) + kq(a)) + f(a) \]
\[ = h(b \cdot x) + b \]

Conversely, if \( h \) satisfies \((C1)\), then we have to prove that the map defined by
\[ \tilde{h}(a) = hq(a) + f(a) \]
preserves addition and conjugation.

We have that
\[ \tilde{h}(a + a') = hq(a + a') + f(a + a) \]
\[ = h(q(a) + q(rf(a) + q(a))) + f(a) + f(a'), (by 2.4(c)) \]
\[ = hq(a) + hq(rf(a) + q(a)) + f(a) + f(a') \]
\[ = hq(a) + h(f(a) \cdot q(a')) + f(a) + f(a') \]
and
\[ \tilde{h}(a) + \tilde{h}(a) = hq(a) + f(a) + hq(a) + f(a') \]
(by \((C1)) \]
\[ = hq(a) + h(f(a) \cdot q(a)) + f(a) + f(a'). \]

Then, also \( \bar{\tilde{h}}(a) = \tilde{h}(a) \) (see 5.2). \[ \blacksquare \]

We observe that \( A \xrightarrow{f} B \) is called a Schreier reflexive graph in [4], because \((f, r)\) is a Schreier split epimorphism.

In [4] 3.2.3 it is proved that a Schreier reflexive graph in the category \( Mon \) of monoids,

\[
\begin{array}{c}
X \xrightarrow{q} X_1 \xrightarrow{d} X_0 \quad X_0 \xrightarrow{c} X_0
\end{array}
\]

with \( ds = cs = 1_{X_0} \) and \((d, s)\) a Schreier split epimorphism in \( Mon \), is an internal category if and only if the condition

\[ (C') \quad q(sc(x_1) + x) + x_1 = x_1 + x, \]
for \( x_1 \in X_1 \) and \( x \in X = \text{Ker}(d) \), is satisfied. In this case the multiplication

\[
X_1 \times_{X_0} X_1 \xrightarrow{m} X_1
\]

is given by \( m(x_1, x'_1) = kq(x_1) + x'_1 \).

Let us translate these conditions in terms of the Schreier reflexive graph

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\xleftarrow{\tilde{h}} & & \\
\end{array}
\]

considering \( f \) the domain and \( \tilde{h} \) the codomain.

Then

\[
\begin{array}{ccc}
X & \xrightarrow{k} & A & \xrightarrow{f} & B \\
\xleftarrow{\tilde{h}} & & \\
\end{array}
\]

is an internal category in \( \text{Mon} \) if and only if the condition

\((C)\) \( k(q(r\tilde{h}(a) + k(x)) + a = a + k(x) \)

is satisfied for all \( x \in X \) and \( a \in A \). That is

\[
k(\tilde{h}(a) \cdot x) + a = a + k(x).
\]

Then for \( f(a) = \tilde{h}(a') = hq(a') + f(a') \),

\[
m(a, a') = kq(a) + a',
\]

where \( m : A \times_B A \to A \) is the monoid homomorphism that gives the admissibility of the diagram

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B & \xrightarrow{\tilde{h}} & A \\
\xleftarrow{r} & & \xleftarrow{r} & & \\
\end{array}
\]

in the category of monoids.

The fact that \( me_1(a) = m(a, rf(a)) = a \) implies that

\[
k(x) = m(k(x), rfk(x)) = m(k(x), 0).
\]

Also \( me_2(a) = m(r\tilde{h}(a), a) = a \).

Then, for \((a, a')\) such that \( f(a) = \tilde{h}(a') \),
\[ m(a, a') = m(kq(a) + rf(a), a') \]
\[ = m((ka(a), 0) + (rf(a), a')) \]
\[ = m(kq(a), 0) + m(r\tilde{h}(a'), a') \]
\[ = kq(a) + a'. \]

So a monoid homomorphism \( m \) satisfying the prescribed conditions of admissibility has to be defined by
\[ m(a, a') = kq(a) + a', \quad \text{for all } (a, a') \in A \times B \]
and it is clear that \( m(0, 0) = kq(0) + 0 = 0 + 0 = 0 \).

Let us show that the existence of such a morphism \( m \) of monoids implies condition \((C)\): since
\[ (r\tilde{h}(a), a) + (x, 0) = (r\tilde{h}(a) + x, a) \]
then
\[ kq(r\tilde{h}(a) + k(x)) + a = m(r\tilde{h}(a) + k(x), a) \]
\[ = m(r\tilde{h}(a), a) + m(k(x), 0) \]
\[ = a + k(x) \]
Conversely, if condition \((C)\) holds then
\[ m((a_1, a_1') + (a_2, a_2')) = m(a_1 + a_2, a_1' + a_2') \]
\[ = kq(a_1 + a_2) + a_1' + a_2'. \]
\[ m(a_1, a_1') + m(a_2, a_2') = kq(a_1) + a_1' + kq(a_2) + a_2' \]
\[ = kq(a_1) + kq(r\tilde{h}(a_1') \cdot q(a_2)) + a_1' + a_2', \quad \text{(by \((C)\))} \]
\[ = k(q(a_1) + q(rf(a_1) \cdot q(a_2))) + a_1' + a_2', \quad \text{(by \((C)\))} \]
and so \( m \) preserves addition.

**Proposition 5.4.** In the category \( \mathcal{M} \), given a Schreier split epimorphism
\[ X \xrightarrow{q} A \xrightarrow{r} B \]
a morphism \( h : X \to B \) induces an internal category if and only if the following conditions hold:
\[ (C_1) \quad h(b \cdot x) + b = b + h(x), \quad \forall x \in X, \forall b \in B \]
\[ (C_2) \quad h(y) \cdot x + y = y + x, \quad \forall x, y \in X. \]

**Proof:** We first verify that \((C_2) \iff (C)\) and so that, in presence of \((C_1)\), we can conclude that the reflexive graph
is an internal category in \( \text{Mon} \).

\((C) \Rightarrow (C_2)\)

If in \( k(\tilde{h}(a) \cdot x) + a = a + k(x) \) we take \( a = k(y) \) we get

\[ k(\tilde{h}(k(y)) \cdot x) + k(y) = k(y) + k(x) \]

and so, from

\[ k(\tilde{h}k(y) \cdot x + y) = k(y + x), \]

we conclude that \( \tilde{h}k(y) \cdot x + y = y + x \), because \( k \) is injective.

\((C_2) \Rightarrow (C)\)

\[ \tilde{h}(a) \cdot x + a = \tilde{h}(kq(a) + rf(a)) \cdot x + kq(a) + rf(a) \]
\[ = (hq(a) + f(a)) \cdot x + kq(a) + rf(a) \]
\[ = hq(a) \cdot f(a) \cdot x + kq(a) + rf(a), \text{ (by (C_2))} \]
\[ = kq(a) + f(a) \cdot x + rf(a) \]
\[ = kq(a) + q(rf(a) + k(x)) + rf(a) \]
\[ = kq(a) + rf(a) + k(x), \text{ (by 2.4(d))} \]
\[ = a + k(x) \]

Consequently, if \((C_1)\) and \((C_2)\) are satisfied then \( h \) induces an internal category in the category \( \text{Mon} \) of monoids. And in \( \mathcal{M} \)? It remains to check that \( m \) preserves conjugation: for \((a, a') \in A \times_B A\), \( m(\overline{a}, \overline{a'}) = kq(\overline{a}) + \overline{a'} \) and

\[ \overline{m}(a, a') = kq(a) + a' \]
\[ = \overline{a'} + kq(a) \]
\[ = kq(r\tilde{h}(a') + kq(a)) + \overline{a'}, \text{ (by (C))} \]
\[ = kq(rf(\overline{a}) + kq(a)) + \overline{a'} \]
\[ = k(f(\overline{a}) \cdot q(a)) + \overline{a'} \]
\[ = q(\overline{a}) + \overline{a'}, \text{ (by 5.1) } \]

**Proposition 5.5.** In the category \( \mathcal{M} \), given a Schreier split epimorphism

\[ X \overset{q}{\leftarrow} k \ A \overset{r}{\rightarrow} f \ B \]

a morphism \( h : X \rightarrow B \) induces an internal groupoid if and only if the following conditions hold:
(C₁) \( h(b \cdot x) + b = b + h(x) \), \( \forall x \in X, \forall b \in B \)
(C₂) \( h(y) \cdot x + y = y + x \), \( \forall x, y \in X \)
(C₃) \( X is a group and \ -x = (-x). \)

Proof: By (C₁) we have a reflexive graph in \( \mathcal{M} \), \( A \xrightarrow{\tilde{h}} B \), with \( \tilde{h}(a) = hq(a) + f(a) \). Then condition (C₂) is equivalent to the fact that this reflexive graph is an internal category

\[
A \times_B A \xrightarrow{m} A \xrightarrow{\tilde{h}} B
\]

with \( m(a, a') = kq(a) + a' \), for \( f(a)(= dom a) = \tilde{h}(a')(= cod a') \) and so \( m(a, a') = a \circ a' \).

By 3.3.2 in [4] we known that this Schreier category is a groupoid in \( Mon \) if and only if \( X \) is a group.

Let us analyse how the inverses are defined in the “object of morphisms” \( A \). For

\[
\xymatrix{ A \times_B A \ar[r]^{m} \ar@/^/[rr]^{t} & A \ar[r]_{\tilde{h}} & B }
\]

\( t(a) \) is the inverse of \( a \), i.e.

\[
dom(a) = f(a) \xrightarrow{t(a)} \ cod(a) = \tilde{h}(a)
\]

and \( t(a) \circ a = m(t(a), a) = 1_{f(a)} = r\tilde{h}(a) \), \( a \circ t(a) = m(a, t(a)) = 1_{\tilde{h}(a)} = r\tilde{h}(a) \).

We define \( t \) by \( t(a) = -kq(a) + r\tilde{h}(a) \). It has the right domain

\[
\dom(t(a)) = ft(a) = f(-kq(a) + r\tilde{h}(a)) = -fkq(a) + fr\tilde{h}(a) = 0 + \tilde{h}(a) = \tilde{h}(a)
\]

and codomain
Indeed, because $h \cdot X$ and, since $m$, we know that 
\( \text{cod}(t(a)) = \tilde{h}(-kq(a) + r\tilde{h}(a)) \)
\( = -\tilde{h}kq(a) + \tilde{h}r\tilde{h}(a) \)
\( = -hk(a) + \tilde{h}(a) \)
\( = -hq(a) + hq(a) + f(a) \)
\( = f(a). \)

And now we prove that $t(a)$ is the inverse of $a$:
\( m(a, t(a)) = m(a, -kq(a) + r\tilde{h}(a)) \)
\( = kq(a) - kq(a) + r\tilde{h}(a) \)
\( = r\tilde{h}(a) = 1_{\tilde{h}(a)} \)

and
\( m(t(a), a) = m(-kq(a) + r\tilde{h}(a), a) \)
\( = kq(-kq(a) + r\tilde{h}(a)) + a \)
\( = kq(k(-q(a)) + r(hq(a) + f(a)) + a \)
\( = k(-q(a)) + a \)
\( = -kq(a) + kq(a) + r f(a) \)
\( = rf(a) = 1_{f(a)} \)

By 3.3.2 in [4] we know that $t$ is a monoid homomorphism. We have to prove that $t$ preserves conjugation and so that it is a morphism of $\mathcal{M}$.

We have that
\( t(\bar{a}) = -kq(\bar{a}) + r\tilde{h}(\bar{a}) \)
\( = -kq(\bar{a}) + r(\tilde{h}q(\bar{a}) + f(\bar{a})) \)
\( = -k(f(\bar{a}) \cdot q(\bar{a})) + r(h(f(\bar{a}) \cdot q(a)) + f(\bar{a})) \text{ (by 5.1)} \)
\( = k(f(\bar{a}) \cdot (-q(\bar{a}))) + r(f(\bar{a}) + hq(a)) \text{ (by (C1))} \)

\( t(a) = -kq(a) + r(hq(a) + f(a)) \)
\( = r(hq(a) + f(a)) + k(-q(a)) \)
\( = kq(r(hq(a) + f(a)) + k(-q(a)) + rf(r(hq(a) + f(a)) + k(-q(a))) \)
\( = k(hq(a) + f(a) \cdot (-q(a))) + r(f(\bar{a}) + hq(a))) \)
\( = k(f(\bar{a}) \cdot hq(a) \cdot (-q(a)) + r(f(\bar{a}) + hq(a))) \)
\( = k(f(\bar{a}) \cdot (-q(a))) + r(f(\bar{a}) + hq(a)) \)

because $h(\bar{x}) \cdot (-\bar{x}) = (-\bar{x})$.

Indeed,
\( 0 = \bar{x} + (-\bar{x}) \)
\( = \bar{x} + (-\bar{x}) \text{ (by (C3))} \)
\( = h(\bar{x}) \cdot (-\bar{x}) + \bar{x} \text{ (by (C2))} \)

and, since $X$ is a group, $h(\bar{x}) \cdot (-\bar{x}) = -\bar{x} = (-\bar{x})$.
Conversely, if

\[
\begin{array}{c}
A \times_B A \\
\xrightarrow{m} A \\
\xrightarrow{\tilde{h}} B
\end{array}
\]

is a groupoid in \( \mathcal{M} \), and so in \( \text{Mon} \), we know that \( X = \ker f \) is a group and that \( t \) is defined by

\[
t(a) = -kq(a) + r\tilde{h}(a) = -kq(a) + r(hq(a) + f(a)).
\]

Since \( t(\bar{a}) = \overline{t(a)} \), in particular, when \( a = k(x) \),

\[
t(\overline{k(x)}) = -k(\overline{x}) + h(\overline{x}),
\]

\[
\overline{t(k(x))} = k(-x) + h(\overline{x})
\]

and \( t(\overline{k(x)}) = \overline{t(k(x))} \) implies that \( -k(\overline{x}) = k(-\overline{x}) \), that is \( k(-\overline{x}) = k(-\overline{x}) \) and so \( -\overline{x} = -\overline{x} \).

\[
\begin{array}{c}
r_1 \\
r_2 \\
r_2 \end{array}
\]

6. From local to global

To study internal structures in several contexts (protomodular, homological, semi-abelian categories) as well as to obtain there strong properties (see [17] and [18]) it is fundamental that they satisfy the so-called “Smith is Huq” condition: any two equivalent relations on an object centralize each other, or commute, in the sense of Smith-Pedicchio (see [20] and [19]), if and only if their normalizations commute in the sense of Huq ([8]).

The category \( \mathcal{M} \) of conjugation monoids with cancellation satisfies the Smith is Huq condition with respect to Schreier equivalence relations, that is equivalence relations

\[
R \xrightarrow{i_R} X
\]

where \( (r_1, i_R) \), and consequently \( (r_2, i_R) \), is a Schreier split epimorphism.
Proposition 6.1. Consider the following diagram in $\mathcal{M}$

\[
\begin{array}{c}
X & \xrightarrow{q_f} & A \xleftarrow{f} B \xrightarrow{\beta} D, \\
& \downarrow{k} & \downarrow{\alpha} \\
A \times B & \xleftarrow{e_2} & C \xrightarrow{e_1} & \downarrow{p_1} & \downarrow{p_2} & \downarrow{g} & C \\
& & \Downarrow{r} & \Downarrow{\gamma} & \Downarrow{\delta} & \Downarrow{\varepsilon} & \Downarrow{\delta}
\end{array}
\]

with $(f,r)$ and $(g,s)$ Schreier split epimorphisms with kernels $X$ and $Y$, respectively, and $\alpha r = \beta = \gamma s$.

If $\alpha k$ and $\gamma l$ commute then there exists a unique morphism $\varphi : A \times B C \to D$ such that $\varphi e_1 = \alpha$ and $\varphi e_2 = \gamma$.

Proof: These relies on 5.5 in [15] where the result was proved for monoids with operations. This is not the case here because the unary operation does not preserve addition. The morphisms $\alpha k$ and $\gamma l$ Huq-commute if, for all $x \in X$ and $y \in Y$,

\[
\alpha k(x) + \gamma l(y) = \gamma l(y) + \alpha k(x).
\]

Then the morphism $\varphi : A \times B C \to D$ is defined by

\[
\varphi(a, c) = \alpha k q_f(a) + \gamma(c),
\]

for all $a \in A$ and $c \in C$ such that $f(a) = g(c) = b$.

Indeed,

\[
\varphi(a, c) = \varphi(k q_f(a) + r f(a), c) = \varphi(k q_f(a), 0) + \varphi(r f(a), c) = \varphi(k q_f(a), 0) + \varphi(r g(c), c) = \alpha k q_f(a) + \gamma(c)
\]

is such that $\varphi e_1 = \alpha$ and $\varphi e_2 = \gamma$. Furthermore, it was proved in 5.5 [15] that $\varphi$ is a monoid homomorphism. It remains to prove that $\varphi$ preserves conjugation.
For \((a, c) \in A \times_B C\),
\[
\varphi(\bar{a}, \bar{c}) = \alpha k q f(\bar{a}) + \gamma(\bar{c}) \\
= \alpha k q f(k q f(a) + r f(a)) + \gamma(\bar{c}) \\
= \alpha k q f(r f(\bar{a}) + k q f(a)) + \gamma(l q g(\bar{c}) + s g(\bar{c})) \\
= \alpha k q f(r f(\bar{a}) + k q f(a)) + \gamma l q g(\bar{c}) + \gamma s g(\bar{c}) \\
= \gamma l q g(\bar{c}) + \alpha k q f(r f(\bar{a}) + k q f(a)) + \alpha r f(\bar{a}), \ (\gamma l \text{ and } \alpha k \text{ commute}) \\
= \gamma l q g(\bar{c}) + \alpha(k q f(r f(\bar{a}) + k q f(a)) + r f(\bar{a})) \\
= \gamma l q g(\bar{c}) + \alpha(r f(\bar{a}) + k q f(a)), \ (by \ 1.4 \ (d)) \\
= \gamma l q g(\bar{c}) + \alpha r f(\bar{a}) + \alpha k q f(a) \\
= \gamma l q g(\bar{c}) + \gamma s g(\bar{c}) + \alpha k q f(a) \\
= \gamma(l q g(\bar{c}) + s g(\bar{c})) + \alpha k q f(a), \ ((g, s) \text{ is Schreier split epi}) \\
= \gamma(\bar{c}) + \alpha k q f(a)
\]
and
\[
\varphi(a, c) = \alpha k q f(a) + \gamma(c) = \gamma(\bar{c}) + \alpha k q f(a). \qed
\]

Given two equivalence relations \(R\) and \(S\) on an object \(X\)
\[
R \xleftarrow{r_1} \overset{i_R}{\xrightleftharpoons{s_1}} X \xleftarrow{r_2} \overset{i_S}{\xrightleftharpoons{s_2}} S,
\]
they commute if and only the diagram
\[
\begin{array}{ccc}
R & \xleftarrow{r_2} & X \xleftarrow{s_1} S \\
\downarrow{i_R} & & \downarrow{i_S} \\
X & & X \\
\downarrow{r_1} & & \downarrow{s_2}
\end{array}
\]
is admissible. Then if \((r_2, i_R)\) and \((s_1, i_S)\) are Schreier split epimorphisms, by 5.1. we conclude that if \(r_1 \ker(r_2)\) and \(s_2 \ker(s_1)\) commute in the sense of Huq then the Schreier equivalence relations \(R\) and \(S\) commute. Since the converse is always true in a weakly Mal’tsev category we conclude that \(\mathcal{M}\) satisfies a relative “Smith is Huq” property:

**Theorem 6.2.** In the category \(\mathcal{M}\) of conjugation monoids with cancellation two Schreier equivalence relations on an object commute if and only if their normalizations commute.
We consider now the case where just one of the split epimorphisms is a Schreier split epimorphism.

**Proposition 6.3.** Let \((f, r)\) be a Schreier split epimorphism with kernel \(k\) and retraction \(q\) in the category \(\mathcal{M}\). Then for the diagram

\[
\begin{array}{c}
A \times_B C \xrightarrow{e_2} C \\
\downarrow p_1 \quad \downarrow p_2 \\
X \xrightarrow{q} A \xleftarrow{r} B \xrightarrow{\beta} D,
\end{array}
\]

with \(fr = gs = 1_B, \alpha r = \gamma s = \beta\), the following conditions are equivalent:

(i) There exists a morphism \(\varphi : A \times_B C \to D\) such that \(\varphi e_1 = \alpha\) and \(\varphi e_2 = \gamma\).

(ii) There exists a morphism \(\varphi : A \times_B C \to D\) such that \(\varphi < k, 0 \geq \alpha k\) and \(\varphi e_2 = \gamma\).

(iii) For all \(x \in X\) and \(c \in C\), \(\alpha k (g(c) \cdot x) + \gamma(c) = \gamma(c) + \alpha k(x)\).

**Proof:** (i) \(\Rightarrow\) (ii) is obvious. To prove the converse we observe that since \((f, r)\) is a Schreier split epimorphism then \((k, r)\) is a jointly strongly epimorphic pair ([4], 2.1.6) and so, since \(\varphi e_1 k = \varphi < k, 0 \geq \alpha k\) and \(\varphi e_1 r = \varphi e_2 s = \gamma s = \alpha r\) then \(\varphi e_1 = \alpha\). And \(\varphi e_2 = \gamma\).

The morphism \(\varphi\), if it exists, is defined by

\[\varphi(a, c) = \alpha k q(a) + \gamma(c)\]

because

\[
\begin{align*}
\varphi(a, c) & = \varphi(kq(a) + rf(a), c) \\
& = \varphi(kq(a), 0) + \varphi(rf(a), c) \\
& = \varphi(kq(a), 0) + \varphi(rg(c), c) \\
& = \alpha k q(a) + \gamma(c).
\end{align*}
\]

Then \(\varphi(a_1, c_1) + \varphi(a_2, c_2) = \alpha k q(a_1) + \gamma(c_1) + \alpha k q(a_2) + \gamma(c_2)\) and

\[
\begin{align*}
\varphi(a_1 + a_2, c_1 + c_2) & = \alpha k(q(a_1) + q(rg(c_1) + kq(a_2)))) + \gamma(c_1 + c_2) \\
& = \alpha k q(a_1) + \alpha k q(rg(c_1) + kq(a_2)) + \gamma(c_1) + \gamma(c_2).
\end{align*}
\]
Thus \( \varphi(a_1 + a_2, c_1 + c_2) = \varphi(a_1, c_1) + \varphi(a_2, c_2) \) if and only if
\[
\alpha k q (r g(c_1) + k q(a_2)) + \gamma (c_1) = \gamma(c_1) + \alpha k q( a_2)
\]
that is if and only if \((iii)\) holds.

And \((iii) \iff (i)\) because \(\varphi\) also preserves conjugation: the fact that \(\varphi(a, c) = \varphi(\overline{a}, \overline{c})\) is equivalent to the identity
\[
\alpha k (\overline{f(a)} \cdot q(a)) + \gamma(\overline{c}) = \gamma(c) + \alpha k q(a)
\]
that is \((iii)\) for \(f(\overline{a}) = g(\overline{c})\) and \(x = q(a)\).

Finally, if \(A = C\) and \(r = s\) we are in the case considered in Proposition 5.3 that is we have a reflexive graph
\[
X \xrightarrow{q} X \xleftarrow{f} X_1 \xrightarrow{g} X_0
\]
with \((f, r)\) a Schreier split epimorphism, that is induced by \(h = g k\).

Then, taking \(c = k(y)\) in \((iii)\) we obtain
\[
(iii)\prime \quad \alpha k(h(y) \cdot x) + \gamma k(y) = \gamma k(y) + \alpha k(x)
\]
for all \(x, y \in X\) and so \(\alpha k\) and \(\gamma k\) “Huq-commute” up to the action of \(h(y)\) on \(x\).

Conversely, if \((iii)\) holds then, since \(c = kq(c) + fr(c)\),
\[
\alpha k(g(c) \cdot x) + \gamma (c) = \alpha k(g(kq(c) + fr(c)) \cdot x + \gamma(kq(c) + fr(c)))
\]
\[
= \alpha k(hq(c) \cdot (f(c) \cdot x)) + \gamma kq(c) + \gamma r f(c)
\]
\[
= \gamma k(q(c)) + \alpha k(f(c) \cdot x) + \alpha r f(c) \quad (by (iii)\prime \text{ and } q(c) = y)
\]
\[
= \gamma k(q(c)) + \alpha(k(f(c) \cdot x) + r f(c))
\]
\[
= \gamma k(q(c)) + \alpha (rf(c) + k(x)) \quad (by \ 1.4 \ (d))
\]
\[
= \gamma k(q(c)) + \gamma f(c) + \alpha k(x) \quad (\alpha r = \gamma r)
\]
\[
= \alpha (kq(c) + rf(c)) + \alpha k(x)
\]
\[
= \gamma(c) + \alpha k(x).
\]
Thus we proved the following:
Proposition 6.4. If, in Proposition 6.3, \( A = C \) and \( s = r \) then the diagram

\[
\begin{array}{cccc}
A \times B & \xleftarrow{e_2} & A & \\
p_1 \downarrow & & p_2 \downarrow & \\
X & \xrightarrow{g} & A & \xleftarrow{r} B \\
& \gamma \downarrow & \beta \downarrow & \\
& & D,
\end{array}
\]

is admissible if and only if

\[
\alpha k(h(y) \cdot x) + \gamma k(y) = \gamma k(y) + \alpha k(x), \text{ for all } x, y \in X.
\]

7. Example

The set \( \mathbb{H} \setminus \{0\} \) of non-zero quaternions is a non-commutative group for the usual multiplication. It is cancellative and has conjugation: for \( q = a + bi + cj + dk \) the conjugate is \( \overline{q} = a - bi - cj - dk \).

We recall that the norm of \( q \) is given by \( \|q\| = \sqrt{qq} = \sqrt{a^2 + b^2 + c^2 + d^2} \), is multiplicative, \( \|pq\| = \|p\|\|q\| \), and \( q^{-1} = \frac{\overline{q}}{\|q\|} \) for \( q \neq 0 \).

The sets \( B = \{q \in \mathbb{H} \mid \|q\| = 1\} \) and \( X = \{q \in \mathbb{H} \mid 0 < \|q\| \leq 1\} \) are a conjugation group \( (q^{-1} = \overline{q}) \) and a conjugation monoid, respectively, with cancellation.

We are going to construct a Schreier split epimorphism in \( \mathcal{M} \). For that we consider the monoid action \( \varphi \) of \( B \) on \( X \) defined by \( b \cdot x = bxb^{-1} = b\overline{b} \), the semidirect product \( X \rtimes_\varphi B \) that is the monoid with underlying set \( X \times B \) and operation

\[
(x_1, b_1)(x_2, b_2) = (x_1(b_1 \cdot x_2), b_1 b_2)
\]

and the Schreier split epimorphism of monoids

\[
\begin{array}{cccc}
X & \xleftarrow{\pi_1} & X \rtimes_\varphi B & \xrightarrow{\pi_2} B \\
<1,0> & \xrightarrow{0,1} & \xrightarrow{<0,1>}
\end{array}
\]

We obtain a Schreier split epimorphism in \( \mathcal{M} \) provide we take \( (x, b) = (\overline{b} \cdot \overline{x}, \overline{b}) \).

Indeed,
\[(1) \ (x, b)(x, b) = (\overline{x, b})(x, b)\]
\[
(x, b)(x, b) = (x, b)(\overline{b \cdot \overline{x}, b}) \\
= (x, b)((b \cdot (\overline{b \cdot \overline{x}})), \overline{bb}) \\
= (x(bb \cdot \overline{x}), \overline{bb}) \\
= (\overline{x}, 1) \ (because \ \overline{b} = b^{-1})
\]
\[
(\overline{x, b})(x, b) = (\overline{b \cdot \overline{x}, b})(x, b) \\
= ((\overline{b \cdot \overline{x}})(b \cdot \overline{x}), \overline{bb}) \\
= (\overline{b \cdot \overline{x}x}, \overline{bb}) \\
= (\overline{xx}, 1)
\]

because the center of \(\mathbb{H}\setminus\{0\}\) is \(\mathbb{R}\) and so \(\overline{b(\overline{x}x)b^{-1}} = \overline{b(\overline{x}x)b} = \overline{bb(\overline{x}x)} = \overline{xx}\). And \(x\overline{x} = \overline{xx}\).

\[(2) \ (x, b)(y, c)(x, b) = (y, c)(\overline{y, c})(x, b)\]
\[
(x, b)(y, c)(y, c) = (x, b)(\overline{yy}, 1) \\
= (x(b \cdot \overline{yy}), b) \\
= (x\overline{yy}, b) \ (because \ \overline{yy} \ is \ in \ the \ center \ of \ \mathbb{H})
\]
\[
(y, c)(\overline{y, c})(x, b) = (y, c)(\overline{y, x}, b) \\
= (y\overline{yy}(1 \cdot x), b) \\
= (y\overline{yx}, b)
\]

and \(x\overline{yy} = y\overline{yx} \) in \(\mathbb{H}\).

\[(3) \ (x, b)(y, c) = (y, c)(x, b)\]
\[
(x, b)(y, c) = (x(b \cdot y), bc) \\
= (bc \cdot (x(b \cdot y)), bc)
\]
\[
(\overline{y, c})(\overline{x, b}) = (\overline{c \cdot \overline{y}, c})(\overline{b \cdot \overline{x}, b}) \\
= ((\overline{c \cdot \overline{y}})(\overline{c \cdot (b \cdot \overline{x}))}, \overline{c\overline{b}})
\]

and
\[
\overline{bc \cdot (x(b \cdot y))} = \overline{c\overline{b} \cdot ((b \cdot y)\overline{c})} \\
= \overline{c\overline{b} \cdot ((by\overline{b})\overline{c})} \\
= \overline{c\overline{b} \cdot (by\overline{y})} \\
= \overline{c\overline{b} \cdot by\overline{b}x}bc ((\overline{c\overline{b}}^{-1} = \overline{c\overline{b}} = bc) \\
= c\overline{y}\overline{b}x bc (\overline{bb} = 1)
\[(c \cdot y) (\overline{b} \cdot x) = \overline{c} \cdot (\overline{y} (\overline{b} \cdot x)) \]
\[= \overline{c} \cdot (\overline{y} \overline{b} \overline{x} b) \text{ (since } b^{-1} = \overline{b}) \]
\[= \overline{c} \overline{y} \overline{b} \overline{x} bc \]

and so (3) holds.

Thus \(X \rtimes \varphi B\) belongs to \(\mathcal{M}\) and all monoids homomorphism in the given Schreier split epimorphism in \(\text{Mon}\) preserve conjugation giving rise to a Schreier split epimorphism in \(\mathcal{M}\).

We define \(h : X \rightarrow B\) by \(h(x) = \frac{x}{\|x\|}\) which gives a monoid homomorphism (because the norm is multiplicative) that, furthermore, preserves conjugation.

The morphism \(h\) induces a reflexive graph in the sense of Proposition 5.3 because it satisfies condition \((C_1)\):
\[h(b \cdot x)b = \frac{bxb^{-1}}{\|x\|} \frac{x}{\|x\|} = bh(x).\]

But \(h\) does not satisfy \((C_2)\) in Proposition 5.4 since, in general,
\[h(y) \cdot x \frac{y}{\|y\|} x (\frac{y}{\|y\|})^{-1} \neq yx,\]
and so does not induce an internal category.

Summing up:

**Example 7.1.** Given \(X\) and \(B\) as above, the action \(\varphi\) of \(B\) on \(X\) defined by \(\varphi(b)(x) = bxb^{-1}\) gives rise to a Schreier split epimorphism

\[X \xrightarrow{\pi_1} X \rtimes \varphi \xrightarrow{\pi_2} B\]

in \(\mathcal{M}\) defining \((x, b) = (\overline{b} \cdot \overline{x}, \overline{b})\) in the semidirect product. Then \(h : X \rightarrow B\) defined by \(h(x) = \frac{x}{\|x\|}\) is a morphism in \(\mathcal{M}\) that induces a reflexive graph but not an internal category in the sense of Propositions 5.3 and 5.4, respectively.
