# THE INVERSE HORN PROBLEM 

JOÃO FILIPE QUEIRÓ AND ANA PAULA SANTANA

#### Abstract

Alfred Horn's conjecture on eigenvalues of sums of Hermitian matrices was proved more than 20 years ago. In this note we raise the problem of, given an $n$-tuple $\gamma$ in the solution polytope, constructing Hermitian matrices with the required spectra such that their sum has eigenvalues $\gamma$.

Keywords: Eigenvalues, Hermitian matrices, sums of matrices. Math. Subject Classification (2020): 05E10; 15A18; 15A29.

## 1. Introduction

A classical problem in matrix theory is the following: given three $n$-tuples of real numbers $\alpha=\left(\alpha_{1}, \ldots, \alpha_{n}\right), \beta=\left(\beta_{1}, \ldots, \beta_{n}\right)$ and $\gamma=\left(\gamma_{1}, \ldots, \gamma_{n}\right)$, ordered decreasingly, when is $\gamma$ the spectrum of $A+B$, where $A$ and $B$ are Hermitian with spectra $\alpha$ and $\beta$, respectively? For fixed $\alpha$ and $\beta$, denote by $E(\alpha, \beta)$ the set of possible $\gamma$. Trivially the set $E(\alpha, \beta)$ is compact and connected (as it is the image of the $n \times n$ unitary group under the continuous mapping taking $U$ to the spectrum of $\left.\operatorname{diag}(\alpha)+U \operatorname{diag}(\beta) U^{*}\right)$ and it is contained in the hyperplane defined by the trace condition, which we abbreviate to $\Sigma \gamma=$ $\Sigma \alpha+\Sigma \beta$.
The problem had a long history in the 20th century, starting with H. Weyl [19]. The theme that emerged gradually was that $E(\alpha, \beta)$ should be described by a family of inequalities of the type

$$
\gamma_{k_{1}}+\cdots+\gamma_{k_{r}} \leq \alpha_{i_{1}}+\cdots+\alpha_{i_{r}}+\beta_{j_{1}}+\cdots+\beta_{j_{r}},
$$

where $r \in\{1, \ldots, n\}$ and $i_{1}<\ldots<i_{r}, j_{1}<\ldots<j_{r}, k_{1}<\ldots<k_{r}$.
In short,

$$
\Sigma \gamma_{K} \leq \Sigma \alpha_{I}+\Sigma \beta_{J},
$$

where $I=\left(i_{1}, \ldots, i_{r}\right), J=\left(j_{1}, \ldots, j_{r}\right), K=\left(k_{1}, \ldots, k_{r}\right)$. The question is to identify the right triples $(I, J, K)$.

[^0]The big moment was a 1962 paper by A. Horn [11]. He presented a remarkable conjecture on the set $E(\alpha, \beta)$, which, in sightly changed form, reads as follows.
For a sequence of indices $I=\left(i_{1}, \ldots, i_{r}\right)$, with $1 \leq i_{1}<\ldots<i_{r} \leq n$, write

$$
\rho(I)=\left(i_{r}-r, \ldots, i_{2}-2, i_{1}-1\right) .
$$

Then Horn's conjecture is: $\gamma \in E(\alpha, \beta)$ if and only if

$$
\left\{\begin{array}{l}
\Sigma \gamma=\Sigma \alpha+\Sigma \beta, \\
\Sigma \gamma_{K} \leq \Sigma \alpha_{I}+\Sigma \beta_{J} \text { whenever } \\
\quad \rho(K) \in E(\rho(I), \rho(J)) \quad \text { (for all } r, 1 \leq r<n) .
\end{array}\right.
$$

The conjecture is now a theorem. So $E(\alpha, \beta)$ is described recursively and is a convex polytope. We refer the reader to two excellent surveys on this story, by Fulton [9] and Bhatia [2].

## 2. An open problem

A natural question concerns the inverse problem, that is, construction of solutions: given $\alpha, \beta$, and $\gamma \in E(\alpha, \beta)$, find Hermitian $A$ with spectrum $\alpha$ and $B$ with spectrum $\beta$ such that $A+B$ has spectrum $\gamma$. In the remainder of this note we make some comments on this open problem and give a few references.
Given the drop in dimension it is to be expected that, for each $\gamma$, there may be many solutions. Since the proof of Horn's conjecture, several authors have studied a question related to the inverse problem: finding the probability distribution of $\gamma$, for given $\alpha$ and $\beta$, using the fact that, as mentioned before, $\gamma$ is a continuous function on the unitary group, where we can take the Haar measure.
References on this, some very recent, are [5], [6], [7], [8], [17], [20], [21].

## 3. Two particular cases

Only one paper - that we know of - addresses the actual construction problem. In [4], the authors use semidefinite programming and give an algorithm that works for $n=3$. (The case $n=2$ is trivial.)
In a different spirit, we can find an exact solution in a very particular case. Without loss of generality, we may assume the $\alpha$ 's, the $\beta$ 's and the $\gamma$ 's are $\geq 0$. We proceed to address the case $\beta_{2}=\cdots=\beta_{n}=0$. So the second matrix to be constructed has rank 1. (By translation, this covers the case where $\beta$ has $n-1$ coordinates equal.)

In this situation the Horn inequalities reduce to

$$
\begin{gathered}
\gamma_{1}+\cdots+\gamma_{n}=\alpha_{1}+\cdots+\alpha_{n}+\beta_{1}, \\
\gamma_{1} \geq \alpha_{1} \geq \gamma_{2} \geq \alpha_{2} \geq \cdots \geq \gamma_{n} \geq \alpha_{n} .
\end{gathered}
$$

Put $D_{\alpha}=\operatorname{diag}(\alpha)$. We are going to find a (real) column $x$ such that $D_{\alpha}+x x^{T}$ has spectrum $\gamma$. Clearly $\|x\|^{2}=\beta_{1}$.

Put $C=\left[\sqrt{D_{\alpha}} x\right]$. We have

$$
D_{\alpha}+x x^{T}=\left[\begin{array}{ll}
\sqrt{D_{\alpha}} & x
\end{array}\right]\left[\begin{array}{c}
\sqrt{D_{\alpha}} \\
x^{T}
\end{array}\right]=C C^{T} .
$$

Therefore, we are looking for a column $x$ such that $C$ has singular values $\sqrt{\gamma_{1}}, \ldots, \sqrt{\gamma_{n}}$. We may assume the $\alpha$ 's to be all distinct (if $\alpha_{i}=\alpha_{i+1}$ just take $x_{i}=0$ ). Denote by $x^{2}$ the column $\left[x_{1}^{2} x_{2}^{2} \cdots x_{n}^{2}\right]^{T}$.
Denote by $\sigma_{k}(\alpha)$ the $k$-th elementary symmetric function of $\alpha_{1}, \ldots, \alpha_{n}$ and write $\sigma(\alpha)$ for the column $\left[\sigma_{1}(\alpha) \sigma_{2}(\alpha) \cdots \sigma_{n}(\alpha)\right]^{T}$.
In [16] it was proved that

$$
J(\alpha) \cdot x^{2}=\sigma(\gamma)-\sigma(\alpha),
$$

where $J$ is the Jacobian matrix of the elementary symmetric functions.
We have det $J(\alpha)=\prod_{i<j}\left(\alpha_{i}-\alpha_{j}\right)$. Since $\alpha_{1}>\cdots>\alpha_{n}, J(\alpha)$ is nonsingular. In [16] the inverse of $J(\alpha)$ is found and related to the Vandermonde matrix with parameters $\alpha$.
So the column $x$ satisfies $x^{2}=J(\alpha)^{-1} \cdot[\sigma(\gamma)-\sigma(\alpha)]$ and there is a nice simple expression for $x$.
An example: take the triples $\alpha=(6,4,2), \beta=(3,0,0), \gamma=(7,5,3)$. We
get $x=\left[\begin{array}{l}0.6124 \\ 0.8660 \\ 1.3693\end{array}\right]$, so $A=\left[\begin{array}{lll}6 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 2\end{array}\right]$ and $B=\left[\begin{array}{lll}0.3750 & 0.5303 & 0.8385 \\ 0.5303 & 0.7500 & 1.1859 \\ 0.8385 & 1.1859 & 1.8750\end{array}\right]$ solve the problem.

## 4. A possible general approach

A somewhat speculative idea to approach the inverse Horn problem uses the well-known Littlewood-Richardson rule, an object appearing in many settings, starting from representation theory.
Suppose the $n$-tuples $\alpha$ and $\beta$ are integral and nonnegative. Denote by $L R(\alpha, \beta)$ the set of all $n$-tuples $\gamma$ that can be obtained from $\alpha$ and $\beta$ according to the Littlewood-Richardson rule (see e.g. [10, App.A.1]).

In [18] it was proved that $E(\alpha, \beta) \cap \mathbb{Z}^{n} \supseteq L R(\alpha, \beta)$. Shortly afterwards, Knutson and Tao [15] proved a combinatorial theorem that, together with earlier work by Klyachko [13] (which also implies the result in [18], obtained independently), shows that there is in fact equality: $E(\alpha, \beta) \cap \mathbb{Z}^{n}=L R(\alpha, \beta)$, and this leads to a proof of Horn's conjecture. Without going into details (see [9]), the equality gives an idea of why the conjecture should be true, because nonempty intersections of Schubert varieties (which produce inequalities) are governed by the $L R$ rule: using the above notations, we have

$$
\rho(K) \in L R(\rho(I), \rho(J)) \Longrightarrow \Sigma \gamma_{K} \leq \Sigma \alpha_{I}+\Sigma \beta_{J}
$$

Second, the equality suggests a connection to another problem: invariant factors of a product of two matrices over a principal ideal domain. (For more general rings see [3].) Let $R$ be a p.i.d. Consider three $n$-tuples of nonzero elements of $R$

$$
a=\left(a_{n}, \ldots, a_{2}, a_{1}\right), \quad b=\left(b_{n}, \ldots, b_{2}, b_{1}\right), \quad c=\left(c_{n}, \ldots, c_{2}, c_{1}\right)
$$

ordered so that

$$
a_{n}|\cdots| a_{2}\left|a_{1}, \quad b_{n}\right| \cdots\left|b_{2}\right| b_{1}, \quad c_{n}|\cdots| c_{2} \mid c_{1}
$$

The invariant factor problem is: when is $c$ the $n$-tuple of invariant factors of $A B$, where $A$ and $B$ are $R$-matrices with invariant factors $a$ and $b$, respectively?

The problem was solved, not in the same exact language, by Klein in 1968 [12]. First, localize the situation: fix a prime $p \in R$ and work over the local ring $R_{p}$, i.e. work with powers of $p$ :

$$
a_{i} \rightarrow p^{\alpha_{i}}, b_{i} \rightarrow p^{\beta_{i}}, c_{i} \rightarrow p^{\gamma_{i}}
$$

where $\alpha_{1} \geq \cdots \geq \alpha_{n}, \beta_{1} \geq \cdots \geq \beta_{n}, \quad \gamma_{1} \geq \cdots \geq \gamma_{n}$ are nonnegative integers. Denote by $\operatorname{IF}(\alpha, \beta)$ the set of possible $\gamma$ in the invariant factor product problem. Then Klein's result states that

$$
I F(\alpha, \beta)=L R(\alpha, \beta)
$$

So $E(\alpha, \beta) \cap \mathbb{Z}^{n}=I F(\alpha, \beta)$. But in [1] there is a constructive version of Klein's theorem. Our speculative question is then: is there a way of "transporting" this construction from the invariant factor setting to Hermitian matrices for the case of integral $\alpha, \beta, \gamma$ ? In this context, it is relevant to note that the equality $E(\alpha, \beta) \cap \mathbb{Z}^{n}=L R(\alpha, \beta)$ reflects a deep result, the

Kirwan-Ness theorem, relating symplectic geometry to geometric invariant theory. (See [14].)
