How to approximate the fractional derivative of order $1 < \alpha \leq 2$

E. Sousa *

* CMUC, Department of Mathematics, University of Coimbra, 3001-454 Coimbra, Portugal

Abstract: The fractional derivative of order $\alpha$, with $1 < \alpha \leq 2$ appears in several diffusion problems used in physical and engineering applications. Therefore to obtain highly accurate approximations for this derivative is of great importance. Here, we describe and compare different numerical approximations for the fractional derivative of order $1 < \alpha \leq 2$. These approximations arise mainly from the Grünwald-Letnikov definition and the Caputo definition and they are consistent of order one and two. In the end some numerical examples are given, to compare their performance.

Keywords: Diffusion, fractional derivative, finite differences, consistency, accuracy.

1. INTRODUCTION

The fractional derivative of order $\alpha$ for $1 < \alpha \leq 2$ in diffusion problems is related to the mechanism of superdiffusion. There are many analytical techniques to solve fractional equations. But in many cases the reasonable approach is to use numerical methods since the problems have initial conditions, boundary conditions and source terms that turns difficult to find an analytical solution.

Different models using fractional derivatives have been proposed and there has been significant interest in developing numerical schemes to find their approximated solution. Some papers where the evidence of fractional diffusion is discussed are for instance Benson et al. (2000), Pachepsky et al. (2000), Zhou et al. (2003), Huang et al. (2006). Many numerical methods involving the fractional derivative that describes diffusion differ essentially in the way the fractional derivative is discretized, see for instance, Shen et al. (2005), Tadjeran et al. (2006), Yuste et al. (2005), Sousa (2009), Zhang et al. (2007).

Approximations of fractional derivatives have more complex formulas than the integer derivatives, since the fractional derivative is non-local, that is, the calculation at a certain point involves information of the function further out of the region close to that point. Consequently the finite difference approximations of the fractional derivative involve a number of points that changes according to how far we are from the boundary.

This paper considers the different approaches presented in the literature and compare their truncation errors and order of consistency.

2. FRACTIONAL DERIVATIVES

We start to introduce different definitions of the fractional derivative. There are a number of interesting books describing the analytical properties of fractional derivatives, such as, Kilbas et al. (2006), Oldham et al. (1974), Podlubny (1999) and Samko et al. (1993).

The usual way of representing the fractional derivatives is by the Riemann-Liouville formula. The Riemann-Liouville fractional derivative of order $\alpha$, for $x \in [a, b]$, is defined by

$$D_{RL}^\alpha u(x) = \frac{1}{\Gamma(n-\alpha)} \frac{d^n}{dx^n} \int_a^x u(\xi)(x-\xi)^{n-\alpha-1}d\xi,$$

where $\Gamma(\cdot)$ is the Gamma function, $n-1 < \alpha < n$ and $n = [\alpha] + 1$, with $[\alpha]$ denoting the integer part of $\alpha$.

Another way to represent the fractional derivatives is by the Grünwald-Letnikov formula, that is, for $\alpha > 0$

$$D_{GL}^\alpha u(x) = \lim_{\Delta x \to 0} \frac{1}{\Delta x^n} \sum_{k=0}^{\lfloor x/\Delta x \rfloor} (-1)^k \binom{\alpha}{k} u(x-k\Delta x).$$

The Grünwald-Letnikov definition is a generalization of the ordinary discretization formulas for integer order derivatives. If we consider the domain $\mathbb{R}$ the sum in (2) is a series. This series converges absolutely and uniformly for each $\alpha > 0$ and for every bounded function $u(x)$.

The discrete approximations derived from the Grünwald-Letnikov fractional derivative present some limitations. First, they frequently originate unstable numerical methods and henceforth many times a shifted Grünwald-Letnikov formula is used instead, see for instance, Meer-schaert et al. (2004). Another disadvantage is that the order of accuracy of such approaches is never higher than one.

A different representation of the fractional derivative was proposed by Caputo,

$$D_{C}^\alpha u(x) = \frac{1}{\Gamma(n-\alpha)} \int_a^x \frac{d^n u(\xi)}{d\xi^n} (x-\xi)^{n-\alpha-1}d\xi,$$

where $n-1 < \alpha < n$ and $n = [\alpha] + 1$. The Caputo representation has some advantages over the Riemann-
Liouville representation. The most well known is related with the fact that very frequently the Laplace transform method is used for solving fractional differential equations. The Laplace transform of the Riemann-Liouville derivative leads to boundary conditions containing the limit values of the Riemann-Liouville fractional derivatives at the lower terminal \( x = a \). In spite of the fact that mathematically such problems can be solved, there is no physical interpretation for such type of conditions. On the other hand the Laplace transform of the Caputo derivative imposes boundary conditions including integer-order derivatives at the lower point \( x = a \) which usually are acceptable physical conditions. Another advantage is that the Caputo derivative of a constant is zero, whereas for the Riemann-Liouville is not.

In the next propositions we state that by requiring a reasonable behavior of the function \( u(x) \) and its derivatives, we can relate the three definitions. These results can be found respectively in Podlubny (1999) and Kilbas et al. (2006).

Proposition 1. Let us assume that the function \( u(x) \) is \((n-1)\) times differentiable in \([a, b]\) and that the \(n\)-th derivative of \(u(x)\) is integrable in \([a, b]\). Then, for every \(n-1 < \alpha < n\) we have

\[
D^\alpha_{\text{GL}} u(x) = D^\alpha_{\text{RL}} u(x), \quad a \leq x \leq b.
\]

Proposition 2. Let us assume that the function \(u(x)\) is a function for which the Caputo fractional derivative \(D^\alpha_{\text{C}} u(x)\) exists together with the Riemann-Liouville fractional derivative \(D^\alpha_{\text{RL}} u(x)\) in \([a, b]\). Then, for every \(n-1 < \alpha < n\) we have, for \(a \leq x \leq b\),

\[
D^\alpha_{C} u(x) = D^\alpha_{\text{RL}} u(x) - \sum_{k=0}^{n-1} \frac{d^k u}{dx^k}(a) \frac{(x-a)^{-\alpha+k}}{\Gamma(-\alpha+k+1)}.
\]

A modified definition of the Riemann-Liouville derivative was introduced recently by Jumarie (2006). Although this formulation may not have advantages compared with the Caputo derivative in what concern numerical discretizations, we think it is worth mention. For \(n-1 < \alpha < n\) is given by

\[
D^\alpha_{C} u(x) = \frac{1}{\Gamma(n-\alpha)} \times
\]

\[
\frac{d}{dx} \int_{a}^{x} \left(\frac{d^{n-1}u}{dx^{n-1}}(\xi) - \frac{d^{n-1}u}{dx^{n-1}}(a)\right) (x-\xi)^{n-\alpha-2} d\xi.
\]

The main difference is that this definition does not require the existence of the derivative of order \(n\) as is required by the Caputo derivative.

### 3. DISCRETIZATION OF THE FRACTIONAL DERIVATIVES

In this section, we describe different ways of discretizing the fractional derivative.

#### 3.1 Grünwald-Letnikov approximations

Let us define the mesh points\( x_j = a + j\Delta x, \ j = 0, 1, \ldots, N \) where \( \Delta x \) denotes the uniform space step.

The Grünwald-Letnikov formulae can lead immediately to the approximation

\[
D^\alpha_{\text{GL}} u(x_j) = \frac{1}{\Delta x^\alpha} \sum_{k=0}^{j} \omega_k^{(\alpha)} u(x_{j-k}),
\]

for

\[
\omega_k^{(\alpha)} = (-1)^k \binom{\alpha}{k} = (-1)^k \frac{\alpha(\alpha-1)\ldots(\alpha-k+1)}{k!}
\]

\[
= \frac{\Gamma(k-\alpha)}{\Gamma(\alpha-k+1)}.
\]

To implement the fractional difference method it is necessary to compute the coefficients \(\omega_k^{(\alpha)}\), where \(\alpha\) is the order of fractional differentiation. For that we can use the recurrence relationships

\[
\omega_0^{(\alpha)} = 1; \quad \omega_k^{(\alpha)} = \left(1 - \frac{\alpha + 1}{k}\right) \omega_{k-1}^{(\alpha)}, \ k = 1, 2, 3, \ldots
\]

This approach is suitable for a fixed value of \(\alpha\). In some problems where \(\alpha\) must be found, various values of \(\alpha\) need to be considered and this may be not the most appropriated way. Instead of that relation we can use the fast Fourier transform method.

When discretizing fractional differential equations we observe that in the literature the shifted Grünwald-Letnikov formula is exhaustively used, since, as already mentioned, the numerical approximations based in the unshifted formula very frequently originates unstable numerical methods.

The shifted Grünwald-Letnikov formula is given by

\[
D^\alpha_{\text{GLS}} u(x_j) = \frac{1}{\Delta x^\alpha} \sum_{k=0}^{j} \omega_k^{(\alpha)} u(x_{j+1-k}).
\]

In the next result we give the leading term of the truncation error for both approaches and observe that although they have the same order of consistency, \(O(\Delta x)\), they are slightly different.

Assuming that \(u(x)\) is a function that can be written in the form of a power series

\[
u(x) = \sum_{m=0}^{\infty} a_m x^m,
\]

we can compare their truncation errors by observing the behavior for each function of the form \(u_m(x) = x^m\).

Proposition 3. Let \(u_m(x) = x^m\). Then

\[
D^\alpha_{\text{GL}} u_m(x_j) = D^\alpha_{\text{GLS}} u_m(x_j) + \Delta x \sum_{j=0}^{N-1} \frac{(m-1-\alpha) \Gamma(m-\alpha)}{\Gamma(m)} x_j \frac{x_{j+1}^{(m-1-\alpha)}}{\Gamma(m)}
\]
Technically = It is easy to see that in this case it makes sense to choose $p$ functions, Taylor series expansions of the corresponding generating function (1 considered as the coefficients of the power series for the $\sum x^k \frac{e^{\Delta x}}{\Delta x}$ or $\sum x^k \frac{\theta^\Delta x}{\Delta x}$).

The coefficients $\omega_k^{(m)}$ as noted by Lubich (1986) can be obtained up to the sixth order in the form

$$D_{\alpha}^\Delta x u(x_j) = \frac{1}{\Delta x^\alpha} \sum_{k=0}^{j} \omega_k^{(m)} u(x_{j-k}) + \frac{1}{\Delta x^\alpha} \sum_{k=0}^{j} \omega_j^{(m)} u_{k}.$$ (13)

The coefficients $\omega_k^{(m)}$ are respectively the coefficients of the Taylor series expansions of the corresponding generating functions, $f_p(z)$, being $p$ the order of consistency. For $p = 2$, the function is given by

$$f_2^\alpha(z) = \frac{z^\alpha}{2}.$$ (14)

Technically all the coefficients $\omega_k^{(m)}$ can be computed using any implementation of the fast Fourier transform. For $s' = 0$, the coefficients $\omega_j^{(m)}$ can be constructed such that

$$\omega_j^{(m)} = \sum_{k=1}^{s} \omega_{jk}^{(m)}.$$ (15)

It is easy to see that in this case it makes sense to choose $s = p$.

The implementation of the fast Fourier transform consist of the following. If $f(z)$ is an analytic function in the closed unit disk, then its Taylor series converges there, and the Taylor coefficients can be computed by Cauchy integrals:

$$f(z) = \sum_{k=0}^{\infty} a_k z^k, \quad a_k = \frac{1}{2\pi i} \int_{|z|=1} z^{-k-1} f(z) dz, \quad (15)$$

where the contour of integration is the unit circle traversed once counterclockwise.

Setting $z = e^{i\phi}$, with $dz = i e^{i\phi} d\phi$ shows that an equivalent expression for $a_k$ is

$$a_k = \frac{1}{2\pi} \int_{0}^{2\pi} e^{-ik\phi} f(e^{i\phi}) d\phi.$$ (16)

These coefficients can be evaluated by the fast Fourier transform.

In our particular case the analytic function $f_p^\alpha(z)$ is

$$f_p^\alpha(z) = \sum_{k=0}^{\infty} \omega_k^{(m)} z^k,$$ (17)

with the coefficients given by

$$\omega_k^{(m)} = \frac{1}{2\pi} \int_{0}^{2\pi} e^{-ik\phi} f_p^\alpha(e^{i\phi}) d\phi.$$ (18)

Note that for $\alpha = 2$ the coefficients $\omega_k^{(m)}$ can be easily obtained. For instance, for $p = 2$

$$\omega_0^{(2)} = 1, \quad \omega_1^{(2)} = -2, \quad \omega_2^{(2)} = 1, \quad \omega_3^{(2)} = 0, \quad k \geq 3 \quad \text{and for } \alpha = 2\quad \omega_0^{(2)} = \frac{9}{4} \quad \omega_1^{(2)} = -6, \quad \omega_2^{(2)} = 11, \quad \omega_3^{(2)} = 0, \quad k \geq 5$$

According to Lubich (1986), we have the following result.

Proposition 4. For any function $u(x)$ sufficiently differentiable, the approximation $D_{\alpha}^\Delta x u(x_j)$, satisfies

$$D_{\alpha}^\Delta x u(x_j) - D_{\alpha}^\Delta x u(x_{j-1}) = O(\Delta x^p).$$

uniformly for $x \in [a, b], 0 < a < b < \infty$.

3.3 Caputo approximations

In this section we derive numerical approximations based on the Caputo derivative definition,

$$D_{\alpha}^\Delta x u(x) = \frac{1}{\Gamma(2-\alpha)} \int_{0}^{x} \frac{d^2 u}{d\xi^2} (\xi)(x - \xi)^{1-\alpha} d\xi.$$ (19)

For each $x_j$, we have that

$$D_{\alpha}^\Delta x u(x_j) = \frac{1}{\Gamma(2-\alpha)} \sum_{k=0}^{j-1} \int_{x_k}^{x_{k+1}} \frac{d^2 u}{d\xi^2} (\xi)(x_j - \xi)^{1-\alpha} d\xi.$$ (20)

An usual way of approximating the Caputo derivative $D_{\alpha}^\Delta x u(x_j)$ is by
We consider the second order derivative of (23) can be approximated by $\delta^2 u_j / \Delta x^2$ where $\delta^2$ is the central second order differential operator

$$
\delta^2 u_j = u(x_{j+1}) - 2u(x_j) + u(x_{j-1}).
$$

Additionally, we also need to know the value of the second order derivative at the boundary point $x_0$. If we have a physical boundary condition of the type

$$
\frac{d^2u}{dx^2}(x_0) = b_0
$$

we can consider the given value. If this value is not available at $x = x_0$ the second order derivative can be approximated by $\delta_0 U_0 / \Delta x^2$ where $\delta_0$ is the operator

$$
\delta_0 u_j = 2u(x_j) - 5u(x_{j+1}) + 4u(x_{j+2}) - u(x_{j+3}).
$$

Finally, an approximation for $D_C^\alpha(x_j)$ can be written as

$$
D_C^\alpha \Delta x u(x_j) = \frac{\Delta x^{-\alpha}}{\Gamma(4-\alpha)} \left\{ a_{j,0} \delta_0 u_0 + \sum_{k=1}^j a_{j,k} \delta^2 u_k \right\}.
$$

We have the following:

Proposition 6. Let $u(x)$ be a function in $C^3[a,b]$ and $1 < \alpha < 2$. Then

$$
D_C^\alpha \Delta x u(x_j) = D_C^\alpha u(x_j) + E_C(x_j)
$$

with

$$
|E_C(x_j)| \leq \frac{2(x_j - a)^2 - \alpha}{\Gamma(3-\alpha)} O(\Delta x^2).
$$

Note that

$$
D_C^\alpha u(x) = D_R^\alpha u(x) - \sum_{k=0}^1 \frac{d^k u(x - a)^{-\alpha+k}}{d x^k (\Gamma(-\alpha+k+1))}.
$$

that is

$$
D_R^\alpha u(x) = D_C^\alpha u(x) + u(a) \frac{(x-a)^{-\alpha}}{\Gamma(-\alpha+1)} + u'(a) \frac{(x-a)^{-\alpha+1}}{\Gamma(-\alpha+2)}.
$$
If we want a first order approximation for the derivative \( D^n_{RL} u(x) \), we can use a first order approximation to determine \( u'(x) \) by using the forward operator

\[
\Delta_+ u(x_j) = u(x_{j+1}) - u(x_j)
\]

and

\[
u'(x_j) = \frac{\Delta_+ u(x_j)}{\Delta x} + O(\Delta x).
\]

On the other hand if we want a second order approximation for the Riemann-Liouville derivative we can use the second order approximation for the first derivative such as

\[
u'(x_j) = -u(x_{j+2}) + 4u(x_{j+1}) - 3u(x_j) + \frac{\Delta x^2}{2} + O(\Delta x^2).
\]

4. NUMERICAL TESTS

In this section, we present some numerical results. The magnitude of the truncation error is compared for the approximations discussed previously and their order of consistency is confirmed.

4.1 Boundary conditions are zero

Consider the function \( u(x) = x^4 \). We have that, for \( 1 < \alpha \leq 2 \)

\[D_{C}^{\alpha} u(x) = D_{RL}^{\alpha} u(x) = D_{GL}^{\alpha} u(x) = \frac{24}{\Gamma(5-\alpha)} x^4 - \alpha \]

Consider the vectors \( U_{app} = (U(x_0), \ldots, U(x_N)) \), where \( U \) is the approximated solution and \( u_{ex} = (u(x_0), \ldots, u(x_N)) \), where \( u \) is the exact solution. The error is defined by

\[
||u_{ex}(\Delta x) - U_{app}(\Delta x)||_\infty.
\]

In Table 1 we compare the first order approximations and in Table 2 we compare the second order approximations for \( \alpha = 1.8 \). We observe in Table 1, that the approximation based in the shifted Grünwald-Letnikov formula gives the accuracy if we consider \( s = 0 \) in (13), since there was no significant differences in the precision if we consider \( s = 1 \).

In Table 3 and 4, we do similar tests to the ones that were done in Table 1 and 2, but now for \( \alpha = 1.2 \). The conclusions are the same.

### Table 3. \( l_\infty \) error (29) for \( \alpha = 1.2, 0 \leq x \leq 1 \)

<table>
<thead>
<tr>
<th>( \Delta x )</th>
<th>( D_{C}^{\alpha} )</th>
<th>( D_{GL}^{\alpha} )</th>
<th>( D_{RL}^{\alpha} )</th>
</tr>
</thead>
<tbody>

<td>0.1145 \times 10^{-2}</td>
<td>0.1431 \times 10^{-2}</td>
</tr>
</tbody>
</table>

4.2 Nonzero boundary conditions

Let us now consider for \( 0 \leq x < 1 \), the function

\[ u(x) = \frac{x}{(1-x)^{3/2}}, \]

and \( \alpha = 3/2 \). We have that

\[D_{RL}^{\alpha} u(x) = \frac{3x^2 + 18x + 3}{\Gamma(5/2)(1-x)^{3/4}}.\]

Note that

\[u'(x) = \frac{2 + 3x}{2(1-x)^{7/4}}\quad u''(x) = \frac{20 + 15x}{4(1-x)^{9/2}}\]

and therefore

\[u(0) = 0 \quad u'(0) = 1 \quad u''(0) = 5.\]

The solution, \( D_{RL}^{\alpha} u(1/4) \), at \( x = 1/4 \), and considering sixteen digits, is given by \( D_{RL}^{\alpha} u(1/4) = 9.13847819273535 \).

In Table 5 and Table 6 we compare the two approximations based in the Grünwald-Letnikov definition and again its confirmed the shifted formula gives smaller errors.

### Table 5. First order error for \( \alpha = 1.5 \) at \( x = 1/4 \)

<table>
<thead>

</tr>
</tbody>
</table>

Additionally, the approximation \( D_{RL}^{\alpha} u(x) \) starts to perform well for values of \( \Delta x = 1/50 \) and \( \Delta x = 1/500 \) but for quite small \( \Delta x \), such as, \( \Delta x = 1/5000 \) we have accuracy problems. Numerical problems related to this approximation are also reported, for instance, in Diethelm et al. (2004).
and assuming \( u(0) = 0 \) we need to consider the approximation,

\[
D_{RL}^{\alpha, \Delta x} u(x_j) = D_{C,1}^{\alpha, \Delta x} u(x_j) + \frac{u(x_j) - u(x_0)}{\Delta x} x_j^{-\alpha + 1} \frac{1}{\Gamma(-\alpha + 2)},
\]

and to obtain a second order approximation,

\[
D_{RL}^{\alpha, \Delta x} u(x_j) = D_{C,1}^{\alpha, \Delta x} u(x_j) - u(x_2) + 4u(x_1) - 3u(x_0) x_j^{-\alpha + 1} \frac{1}{2\Delta x} \frac{1}{\Gamma(-\alpha + 2)}. \tag{30}
\]

In Table 7 and Table 8 we show the performance of the derivatives \( D_{RL}^{\alpha, \Delta x} u(x) \) and \( D_{RL}^{\alpha, \Delta x} u(x) \) and see that the approximation \( D_{RL}^{\alpha, \Delta x} u(x) \) is quite accurate.

**Table 7. First order error for \( \alpha = 1.5 \) at \( x = 1/4 \)**

<table>

</table>

We conclude the second order approximation based in the Caputo definition is a very good option.

5. CONCLUSION

We have presented and compared different numerical approximations for the fractional derivative. The approximation based in the shifted Grünwald-Letnikov definition is the best option when considering first order approximations. For second order approximations, the approximation obtained from the Caputo definition performed better. Additionally precision problems related with the Lubich approximation are reported. These problems may be a consequence of the fact that we are unable to compute the weights with high accuracy.
